HEARING WORKSHOP AT
STANFORD MEDICAL CENTER

release on receipt

STANFORD -- The first scientific meeting to be held in the partially completed campus quarters of the Stanford Medical Center -- a four-day workshop on the problems of the hard of hearing-- will open next Sunday (July 26).

The workshop is to be jointly sponsored by Stanford's Speech Pathology and Audiology Department and the Hearing Aid Industry Conference, a trade association representing leading hearing aid dealers.

Some 80 hearing aid dealers from the western states and Canada are expected to attend the conference, which is under the direction of Hayes A. Newby, Ph. D., Stanford professor of Speech Pathology and Audiology.

The dealers will undergo an intensive course in the physiology of hearing problems and the newest techniques for mechanically aiding hearing defects. Lectures will be presented by experts from all over the United States.

Participants will include: Doctor Newby; William C. Hardy, director of the Hearing and Speech Center at Johns Hopkins University; E. Thayer Curry, director, Department of Audiology, university of Pittsburgh School of Medicine; Raymond T. Carhart,

- more -

professor of audiology, Northwestern University, and Kenneth O. Johnson, executive secretary of the American Speech and Hearing Association.

The program will include a tour of the Department of Speech Pathology and Audiology, one of the first units to be housed in the still-building, $20,000,000 Stanford Medical Center.

The workshop is one of a series held and planned at various university centers and designed to train hearing aid dealers to aid an estimated 8,500,000 Americans with problems that can be corrected with hearing aids.

NEW ERA OF TREATMENT FOR 'ADULT DELINQUENTS'
SEEN BY VISITING BRITISH PSYCHIATRIST

for release upon receipt

STANFORD, California ** Mentally-ill members of the community will be better served by aid from within the community itself than confinement in penitentiaries or large mental hospitals, a leading British psychiatrist said today.

"Actually, mental hospitals are not the places to treat behavior problems," said Dr. Maxwell S. Jones, Commonwealth visiting professor of psychiatry at the Stanford University School of Medicine.

Jones, a consultant on mental health to the World Health Organization, came to the United States last week to begin work in the Stanford post.

He is the originator of the "therapeutic community" -- a new concept in treatment of mental illness based upon the interaction of groups of psychiatric patients guided by skilled physicians and social workers.

Jones opposed the rigid organization of large mental institutions with the concept of open-door wards treating smaller groups in "democratic equalitarian" environment. He considers

- more -

today's institutions all too often lacking "cohesive, integrated treatment forms" because of their hierarchial structures.

The mental health expert will help pioneer an individual-orientated program of psychiatric care at Stanford, emphasizing interaction of family, patient groups, and the university's basic science research facilities.

Jones called for a change in public attitudes concerning treatment of mental illness. "Up to now, we've simply been trying to get rid of the person who reminds us of the bad parts of ourselves by confining the psychotic and psychopath in large mental hospitals," the British psychiatrist said.

WESTERN PSYCHIATRIC PROFESSORS TO
MEET AT STANFORD MEDICAL CENTER

STANFORD. -- Forty-three of the West's leading psychiatry teachers will gather at the new Stanford Medical Center this week to discuss such professional problems as faculty shortages, salary scales and relationships with other university departments.

The Stanford Medical School's Department of Psychiatry will play host on September 4 and 5 to an "Institute for Professors of Psychiatry West of the Mississippi."

The purpose of the meeting, which is being supported by a grant from the National Institute of Mental Health, is an exchange of views on the academic aspects of psychiatric teaching.

In attendance will be psychiatric department chiefs from most of the universities in the area, as well as other professors.

Included on the agenda are such problems as the necessity of recruiting qualified instructors, departmental budgets, training and residency programs and the teaching of students in non-medical schools.

Dr. Thomas A. Gonda, acting head of the university's department of psychiatry, will act for Stanford as host to the visitors.

NEW STANFORD HOSPITAL FEATURES 24-HOUR 'AUTOMATIC SECRETARY'

for release upon receipt

Insomnia need no longer be an unproductive state for doctors at the new Palo Alto-Stanford hospital.

A unique electronic device located in the multi-million dollar hospital plant in the Stanford Medical Center -- the 'electronic secretary' -- enables physicians to telephone a Central Dictating system at any time in the day, or sleepless hour in the night, and dictate his reports or specialized medical correspondence.

Stenographers transcribe the material the next day, and the finished copy is held at the Doctors' Lounge for proofing and signature.

The modern system will greatly aid physicians in meeting the growing load of paper work required each year.

STANFORD POLIO RESEARCHER

GRANTED FOUNDATION FUNDS

STANFORD -- A Stanford scientist who earlier split a polio virus into infectious and non-infectious parts has been awarded a March of Dimes grant of $29,808 to continue his studies of the structure of the dreaded virus.

Announcement of the grant to Dr. Carlton E. Schwerdt, associate professor of medical microbiology in the Stanford University School of Medicine, was made today by Basil O'Connor, president of the National Foundation.

Doctor Schwerdt has long been noted for his work on purification of the polio virus, particularly the discovery of two fraction which differ in a number of essential ways.

One fraction -- the larger of the two -- produces polio; the other does not. The two also differ antigenically: when injected in animals they provoke the production of different sorts of disease-fighting antibodies.

Doctor Schwerdt plans to continue his investigation of the relationship of the two fractions and possibly other fractions that may be present in the total virus. He also willl attempt to obtain further information on the chemical composition and physical properties of the fractions.

Beyond this point Doctor Schwerdt also will try to learn the sequence in which fractions are built up during the period when a virus is reproducing within an infected cell.

Cells will be broken up at various times after they have been infected, in the hope of isolating the fractions at different stages of development.

All of these studies are aimed at increasing man's knowledge of the nature of virus particles and of the mechanism by which they are manufactured.

Such knowledge may prove of value in devising effective drugs against polio and other virus disease or in the manufacture of vaccines.

FOR RELEASE P. M. Papers of Tuesday, August 25 TELEPHONE DA 1-5310-11

PROGRAM SET FOR STANFORD
MEDICAL CENTER DEDICATION

STANFORD, Aug. 25- Dr. James Shannon, director of the National Institute of Health, and five other noted speakers will highlight the two-day dedication of the new $22,000,000 Stanford Medical Center here on September 17 and 18.

On hand also will be at least one Nobel Prize winner and Governor Edmund G. Brown, according to an announcement released today by Stanford President Wallace Sterling.

While it has been no secret that Stanford Medical School has been moving from its old San Francisco quarters to join in the same sprawling structure with a new Palo Alto-Stanford Hospital, today's was the first announcement of speakers and other details of the big dedication program.

It will include not only Doctor Shannon and Nobel Laureate Joshua Lederberg, head of Stanford's department of genetics, but a whole host of other scientists and dignitaries.

The final public ceremony marking the official opening of the Center will be held in the fountain-sprayed court in front of the building at 8 p.m. on September 18.

-more-

STANFORD DEDICATION 2-2-2

Following an academic procession and a benediction read by Robert M. Minto, the university chaplain, President Sterling will introduce Palo Alto Mayor Noel Porter and David Packard, of Palo Alto, president of the Stanford Board of Trustees.

Following brief talks by these two and an introduction of the Governor, the major address of the evening will be presented by Frank Stanton, president of the Columbia Broadcasting System.

The move of the Stanford Medical School from San Francisco to the campus near Palo Alto is the culmination of a dream long held by President Sterling, Dr. Robert H. Alway, dean of the school, and members of the Board of Trustees -- a dream based on the expectation of the treating of every patient as a "whole" man by doctors who themselves are "whole" men.

The concept has included three major ideas: that medical students ought to be near other university departments so they can absorb a broad knowledge along with the techniques of medicine; that, as a consequence, they will learn to treat "not the ulcer but the man," and the final fruition of a long and pleasant connection between Stanford and the City of Palo Alto.

-more-

Palo Alto's wing of the hospital, which is included in the building and which complements Stanford's teaching hospital at the other end of a central service core, is the result of a $4,000,000 bond issue passed by the city's voters some years ago.

To start off the two-day celebration there will be a welcome address on the morning of September 17 by Doctor Alway, stressing the dedication's theme: "Medical Care, the University and Society."

Doctor Alway will then introduce Doctor Shannon, the Nation's topmost official research director, who will make the keynote address.

Later in the morning there will be other talks by William McPeak, vice-president of the Ford Foundation, and Dr. E. Cowles Andrus, of Johns Hopkins University.

Following luncheon there will be another address, this by Dr. Vernon Lippard, dean of the Yale Medical School.

The other major speech of the weekend ceremony will be that of Lester Evans, president of the Commonwealth Fund, on Friday afternoon.

Throughout the two days, for both scientific and lay audiences, there also will be concurrent lectures on new research discoveries by such famed Stanford scientists as:

STANFORD DEDICATION 4-4-4

1 - Lederberg on "Viruses as Genes."

2 - Dr. Norman Kretchmer, head of Stanford's Department of Pediatrics, on "Heredity, Development and Disease."

3 - Dr. Arthur Kornberg, head of the Biochemistry Department, on "The Chemical Basis of Genetics."

4 - Dr. J. Garrott Allen, head of the Department of Surgery, on "Serum Hepatitis."

5 - Dr. Keith F. Dillon, associate professor of pharmacology, on the "Neuropharmacological Approaches to the Study of Drug Action."

6 - Dr. Edmund H. Volkart, associate professor of sociology, on "Man, Disease and the Social Environment."

Also going on at the same time during all of the two days -- but mainly available to scientific audiences only-- will be a series of seventeen scientific symposia, which will present a cross-section of the research going on at the Center.

STANFORD'S LANE LIBRARY MOVES AUGUST 31

A caravan of 160,000 medical books and journals will travel down Bayshore Freeway August 31st -- September 1.

The books -- some of them over 500 years old -- form Stanford Medical School's Lane Medical Library which is moving to new quarters in the $22,000,000 Stanford Medical Center on campus -- 35 miles south of San Francisco.

Lane Library has traditionally been housed in Stanford Medical School which has also just moved from San Francisco to the campus.

The trek will be the first for the library since 1912 when the present building was opened on Sacramento and Webster Street in San Francisco.

It involves among other things:

--18 "incunabula", some of the earliest printed books, published circa 1450-1500.

--Thousands of medical journals, books and pamphlets in more than a dozen languages.

--Half a million library file cards.

--Relics of early California medicine, including scores of instruments, saddle bag medical kits and other antiques.

--Fifty-thousand pounds of tables, chairs, files and other furniture.

-- more --

Lane Library 2/2/2/2/2/2/2/2/2/2

Twenty-five van loads of books and paraphernalia will make the trip to the new quarters where crews will be waiting to remove the books and place then in proper position in nearly five miles of shelves and stacks.

The task of moving the library has been assigned to Market Street Van & Storage, a long-time San Francisco moving firm.

It is estimated close to 500,000 pounds of books and related library equipment will be moved to the Stanford campus by the time the fall semester commences in late September.

The move is under the supervision of Elmer W. Greider, acting director of University Libraries at Stanford.

An estimated 1,650 man hours of labor is involved.

"An elaborate marking and tagging system has been developed to assure that every book is placed on the right spot on the right shelf," according to Miss Clara Manson, Lane Librarian.

Miss Munson and her staff have been working for several months tagging each shelf with color coded stickers. A duplicate sticker identifies the shelf in the new campus library. The movers will pack a shelf of books to each carton, transfer the sticker from the shelf to the filled carton and send it on its way in a carefully charted sequence to arrive at the right place at the right time at the new Stanford Medical Center. Three thousand specially-designed cartons will be used to carry the books.

"Actually the biggest problem is getting the books out of the library," a spokesman for the moving company said.

A small elevator serves only a limited part of the old Library

--- more ---

building and is much too slow for the pace planned by the movers.

To solve this problem, a "fork-lift" with a two-story reach and a series of shutes to slide the books to ground level will be used.

The priceless collection of "incunabula" will receive special handling. These delicate works will be individually wrapped in tissue paper, cushioned in containers and transported in padded cartons.

#######

Editors: The "fork-lift" used to move the books from the Library windows and the special equipment used to move the rare books may afford picture possibilities.

FOR RELEASE: UPON RECEIPT TELEPHONE DA 1-5310-11

22-MILLION DOLLAR HOME
FOR DISEASE FIGHTERS

Stanford University medical researchers have a new 22-million dollar home in which to continue their fight against death and disease.

The Stanford Medical Center, a sprawling, fifty-six acre complex of three hospital and four medical school buildings on the northern end of the Stanford campus in Palo Alto, California, is equipped with the most modern tools of medical science to further the constant laboratory research necessary to better maintain life and safeguard health.

A seven-million electron volt 'cancer cannon,' one of the latest developments in science's fight against cancer, was transplanted from the basement of Stanford's old Medical School in San Francisco and installed in the modern Palo Alto quarters yesterday. The huge X-ray gun, which treats 20 to 25 patients per day, is a 'baby brother' of the atom-smashing 'Mark IV' linear accelerator already in use on the Stanford campus. The device enables doctors to direct the depth of radiation penetration in treating deep-seated cancers, safeguarding nearby healthy body areas.

Dr. Henry S. Kaplan, head of the radiology department in Stanford's Medical School, called recent X-ray experimentation

-more-

"encouraging", but said the process has not been perfected for general clinical use.

A new X-ray microscope, called the "micro-fluoroscope", was installed in research quarters in the new Medical Center last week. The device allows physicans to view minute cell mechanisms deep within the body.

Stanford heart researchers have made two recent contributions to modern heart surgery. Heart fibrillation--a state in which the heart becomes unable to pump blood--has been the object of intensive sudy by Stanford's Dr. Norman Shumway. Laboratory work with animals has disclosed that a mild electrical shock--slightly stronger than the one used to induce the condition in tests--will revive the heart and restore normal pumping action.

A study of a body-cooling technique in heart surgery is being conducted by Dr. John Connolly of the surgery department. Body-cooling reduces heart activity and slows down body pressures to allow up to eight minutes of open-heart surgery. Dr. Connolly is working on application of the technique to brain surgery.

One of the main motives behind the move of the medical school from its quarters in San Francisco to the Stanford campus was to allow greater inter-action of medical teaching and research with other departments of the University. Formal dedication of the Center will be held September 17-18, but medical researchers have already taken advantage of cooperative work with other Stanford departments.

Research 3/3/3

A study group is investigating the connection between methods of medicine and sociology, and other inter-departmental acitivities are planned.

Many Stanford doctors have already moved their research activities into the new Palo Alto headquarters. Dr. Sidney Raffel, chairman of the medical microboology department, is devoting extensive research to a hitherto undiscovered factor in the blood which may explain susceptibility to tuberculosis. Other medical scientists in the microbiology department are studying allergies and immunological research centering around transplanting human tissues.

A team of research physicians directed by Dr. Rajendra G. Desai has begun a study of stomach cancer in varying racial groups. Experiments are now being conducted with the modern X-ray equipment in the new Medical Center to further knowledge of gradations of immunity and tissue transplanting.

Stanford Medical Center
News Bureau Palo Alto, California

FOR RELEASE: UPON RECEIPT TELEPHONE DA 1-5310-11

STANFORD, California,_____. You may come up with your own reasons for it, but tests at the Stanford Department of Physical Therapy have indicated that high school senior girls are generally stronger than college women.

These are the findings of Marian Williams, Ph.D., associate professor of physical therapy at the Stanford Medical Center.

Professor Williams is engaged in research directed toward evaluating human strength and determining norms of physical performance.

Her work promises to have widespread clinical value as a comparative measure in cases of certain patients whose medical problems have left them at a less than normal performance level.

Professor Williams' work may also soon become a measure of disability and recovery from polio and other performance-affecting afflictions.

The research was carried out with a "dynamometer" perfected for Miss Williams at Wayne State University. The "dynamometer" is a simple ring-type meter for measuring amount of tension or "pull".

Major muscle groups were tested through a range of angular positions for each muscle.

Once the norms are developed and perfected, there may be a use for both Miss Williams scales and apparatus in testing the effects of relaxants and other drugs on strength and performance.

-more-

Preliminary reports from the studies have produced information not generally appreciated about muscle growth and development. They tell of some muscles whose strength increase appears to continue with age, to young adulthood, while that of some others hits a plateau early in life.

The studies have been conducted only on subjects ranging from 6th graders to college students. Additional studies are contemplated over a wider age range.

Professor Williams points out that factors other than strength abilities can have a decided effect on performance. "On a given day, at a given time", she emphasizes, "psychological or neurological factors may affect one's performance". Extensive testing, it is expected, will help to eliminate the effects of these factors in compiling the tables of norms.

Once completed, it is expected additional uses will be found for Miss Williams' work. Physical education classes may well use the tests as a measure of development and an indication of needed training. In a rather far-fetched way, it has been suggested that athletic squads can be compared on the basis of her studies.

"However," Professor Williams points out, "we are primarily interested in clinical applications and I'd rather somebody else developed uses for these tests in other respects."

X-RAYS MAY HELP SKIN GRAFTS

STANFORD, California -- X-rays, which normally diminish the body's ability to resist disease, may become a useful factor in future skin-grafting operations.

Research work at the Stanford Medical Center by Dr. Sidney Raffel -- head of Stanford University's Medical Microbiology Department, is concentrated on finding "the positive good in exposure of the total body to X-rays or shorter wave irradiations."

Raffel's research indicates that potentially negative exposures may greatly aid successful tissue grafting and organ transplantations.

Ordinarily a person will reject tissue transplants from any source but an identical twin, much in the manner a body rejects bacteria or viruses.

Total irradiation has been used to suppress this reaction in cases where transplantation of organs has been vital.

The major difficulty encountered in this type of treatment is that once the body recovers from irradiation damage it will reject or react against the foreign tissues.

If the period of non-responsiveness can be prolonged, studies have shown, the subject may "forget" how to respond against the foreign substances. This is the area of concentration at the present time.

Dr. John Steward and Miss Jacqueline Dickson are aiding Dr. Raffel in the study.

FOR RELEASE: Upon Receipt TELEPHONE DA 1-5310-11

HEART MACHLNE PROGRESS REPORT

Some sunny day in the future a local business executive will suffer an acute heart attack on his way to the 18th tee.

Today this might mean immediate death, but on that day portable heart machines will be rushed to the scene, and may save his life.

This, in essence, is the report of Dr. John Connolly of the Stanford Medical Center.

Research is now under way to make portable, for use in such emergencies, machines which are now functioning as great aides in surgery rooms.

A United States Public Health Service grant has financed Dr. Connolly's studies of mechanical assistance in acute heart failure. The study is now in its second year. His associates in this project are Dr. Marvin Baconer and Dr. David L. Bruns.

In part, the study has produced a portable "bypass kit" consisting of tubing and a pump, an offshoot of the present surgical heart pumping mechanism.

This machine functions to relieve the heart of a part of its load, drawing blood from veins returning it to the heart, and pumping it into arteries which carry it to the rest of the body.

-more-

In its practical application the machine provides rest for the heart which may, in some cases, repair itself. In other cases it serves to prolong a patient's life until required treatment can be given.

An additional aspect of the study includes a hope that the more complex heart-lung machine, which not only pumps blood, but which also oxygenates it (the function of the lungs), may be used in similar cases. Extremely complex cases of heart failure, accompanied by a malfunctioning of the lungs, will eventually necessitate this.

At present there are many obstacles to the quick application of either machine. They require a team of medical technicians and large amounts of blood, and are now impossible to activate on short notice.

Current research -- is directed toward a more adaptable model, and testing its usefullness and practicability.

NEW STANFORD HOSPITAL DESIGNED
FOR PATIENT, NURSE CONVENIENCE

The little things -- the ones that count -- have been installed in the new Palo Alto-Stanford Hospital for the maximum convenience to patients and nurses.

Equipment in each room includes inter-com devices at bedsides, built-in oxygen and suction apparatus, automatic raising and lowering devices on beds, individualized cabinets for clothes and personl belongings, television and telephone.

The hospital, part of the 22-million dollar Stanford Medical Center, a sprawling, fifty-six acre complex of four medical school and three hospital buildings, will be dedicated in two-day ceremonies September 17-18.

Hospital rooms were planned for the convenience of both patients and nurses. "Actually, we have found that anything convenient to the patient is also convenient to the nurse," Darlene Lutts, Deputy Director of Nurses at the hospital, said.

Much of the modern equipment works both ways. The now 'high-low' beds, which can ne rasied and lowered automatically, save a nurse the stiff arms accompanying hand-cranked beds and allows a patient an easy exit by lowering .....

_ MORE _

the bed to the floor. This method does away with the clumsy foot stools previously in use.

Nurses are saved miles of corridor travel a year by the inter-com device which enables a patient to directly communicate his wants to the nurse on duty. This system brings quicker service to the patient.

Built-in wall units which dispense oxygen and pipe in suction to aspirate fluids from body cavities provide immediate relief for a pateint; they also eliminate movement of bulky equipment to the room.

A unique feature of the hospital is the modern hand rails installed along the length of the corridors, enabling patients unsure of their footing a needed pedestrian aid. Hand rails have also been installed in the bathrooms.

Custom-tailored cabinets in the rooms provide patients with adequate storage for their clothes and belongings, and telephones, placed at each bedside, provide patients with independent means to send messages previously relayed by nurses.

An added measure of privacy is afforded patients by special rooms on each floor for individual medical treatments and examinations. This facility eliminates the need for the traditional wheeled screens that surround beds during examinations and ends transportation of bulky equipment into the room.

An outstanding feature of the hospital construction, which utilizes the Peninsula's traditionally mild weather, is

the first floor patios that enable patients to sit in a protected outdoor area and enjoy the sun.

The nurse has not been neglected in the various innovations in the new hospital. A modern system of pneumatic tube transportation speeds messages, drugs, and specimens between buildings and departments, eliminating extended foot travel. Reading lights over patient's beds have been equipped with an adjustable arm providing a nurse with direct lighting for administration of medications.

Specially-equipped medicine rooms on each floor provide a place away from hospital traffic where a nurse may prepare medications. Each patient has an individual cubicle for assigned drugs.

Head nurses have glass-enclosed offices at each nursing station. Nursing stations are equipped with ice-making machines, allowing nurses ready access to filling ice packs. A lounge for off-duty nurses has been built on each floor.

Escalators between floors facilitate inter-departmental travel.

The traditional Red Cross Gray Ladies have also been remembered in hospital planning. A room has been set aside for them to arrange flowers; previously this work was done in cramped utility rooms.

STANFORD TO INSTALL NEW

HEART X-RAY MOVIE DEVICE

STANFORD -- An improved double X-ray motion picture camera, combined with a heart catheter system, is being installed at the new Stanford Medical Center for use by Stanford University researchers.

The new camera permits three-dimensional viewing of the heart in action. It will eventually be used in conjunction with a to-be-installed closed circuit television system which will permit groups of physicians to see it.

Professor Herbert L. Abrams, Stanford radiologist, said the new $100,000 device has advantages former two-plane X-ray motion pictures of the heart did not have.

It also uses 11-inch screens while formerly only 5-inch screens could be used. This permits study of adjacent blood vessels to the heart at the same time that the heart is under observation.

The camera is turned on after a catheter -- a long thin steel tube -- is inserted into the heart through an artery or vein.

Opaque material is then pumped through the catheter into the chamber of the heart and can be followed as it moves with the blood through the heart and blood vessels.

By observing the movement of the blood, scientists can tell how the heart and other vessels are functioning.

- more -

The two screens used in the camera permit photographing of a double strip of film. The films may then either be studied separately or projected together to give a three-dimensional quality to the picture.

The camera device also uses two "Dynapulse" intensifiers which shorten the time a patient need be exposed to X-radiation by "storing" X-rays and releasing them in brief bursts.

Stanford's installation is the first double 11-inch screen system to be installed in the U. S. The screens were built in the Netherlands and have been purchased by other U. S. hospitals, but only for use in single sequence.

BREAKTHROUGH IN HUMAN STERILITY

PREDICTED BY STANFORD SCIENTIST

STANFORD. -- Ten years from now a married couple previously doomed to remain childless by "sterility" may be provided with a family though eggs fertilized in a laboratory and then implanted in the mother's womb.

This prediction was made here today by a Stanford Medical Center gynecologist, Dr. R. W. Noyes, and was based on his own and the research of other fertility experts.

As a careful scientist, Doctor Noyes made no definite promises, but he did point to an experimental breakthrough which portends a relatively simple solution to the problem of so-called sterility.

"Although the period may be a full 10 or 20 years in the future," he said, "we are at a stage believed unattainable not many years ago."

Doctor Noyes' work arises out of the knowledge that only a single male sperm cell is needed to fertilize a single female egg.

Yet the chance of the single sperm reaching and fertilizing the single ovum under natural circumstances is so remote that nature has provided a tremendous excess of sperm over eggs-- literally millions of male cells to each female egg.

Thus a man is presumed to be sterile for all practical reproductive purposes if his sperm count is below 20 million cells per cc. of containing fluid.

Additionally a woman may be sterile -- in the present practical sense of the word -- if disease or malformation prevents her eggs from reaching the site where fertilization normally takes place.

- more -

STERILITY 2-2-2-2

The fact still remains that any one of the 20 million (or fewer) sperm cells can be brought into contact with any single female ovum in the proper sort of environment fertilization can take place.

Doctor Noyes' work has been largely concerned with providing such an environment, and his experiments with single-cell fertilization in mice, rats and rabbits has been satisfactory enought to warrant his confidence that human application is close.

In the animals he has by-passed the uterine tube stage of fertilization in the female on the theory that in human infertility either no ova are present here or not enought sperm cells reach the site to guarantee a fertile meeting.

Instead sperm and eggs from the male and female concerned are brought together for fertilization in uterine tubes excised from other females. (In clinical use these would be available following removal for other causes.)

In the laboratory following this sort of fertilization, the growing eggs are kept alive in tissue cultures.

Their growth can be controlled by temperature changes so that their "age" can be exactly matched to the cycle of the mother.

When this matching point arrives, the fertilized egg is implanted in the womb of the mother, and from there on the normal process of child-bearing takes over.

Doctor Noyes emphasized that much of the early work with the method has been done by other research groups. His own specific contribution has been in the field of defining the environmental conditions needed for fertilization (completely artificial uterine tubes may some day be substituted for those remobed from other females) and determining exact degrees of egg growth -- in order that implanting may be done at the right moment. #### jfa

STANFORD RESEARCH POINTS TOWARD
CHEMICAL BARRIER AGAINST TB

STANFORD. -- Your chance of catching tuberculosis may depend primarily on the level in your blood of a still un-named factor recently discoverd by a Stanford Medical Center research physician.

Increasing evidence of this direct relationship between blood levels of the factor and susceptibility to the disease was reported today by Dr. Sidney Raffel, head of the Medical Microbiology Department of the Stanford School of Medicine.

The report was based on a check of the factor levels of an entire medical school class of 60 students.

At the same time Doctor Raffel reported that there "is already some indication that the blood level of the factor may be raised by certain chemical means."

There is the possibility, he added, that people who face exposure to TB can be given extra protection against infection through the administering of the chemical stimulator.

Doctor Raffel first reported his discovery of the blood fraction last April. It came, he reported, as the result of a happy accident.

While working on another experiment, Doctor Raffel discovered that the factor -- which he had isolated and purified -- killed TB bacilli in the test tube.

- more -

This was an exciting discovery, since tough-shelled little tuberculosis germs are almost indestructible -- one of the reasons why TB is never entirely cured, but only held in check.

A hurried check of available patients seemed to confirm Doctor Raffel's hunch that there was a relationship between the fraction level and an individual's chances of catching the disease. But he needed sharper proof.

So he used one entire class of Stanford medical students. Of the 60 first tuberculin tested, 21 were positive -- that is, they had been exposed to TB and had the disease, although not in an active state.

The 39 who showed negatibe reactions -- indicating a lack of the disease -- all were given BCG, a TB imunizing agent made up of attenuated vacilli, strong enough to change negatives to positives but not strong enough to create a diseased state.

In every case, Doctor Raffel said, the level of the factor in the blood was higher after the BCG immunization than before.

Whether or not the level is already higher in those individuals who resist exposure and who have not been actually challenged with the bacilli or vaccine is still unknown.

Doctor Raffel and his group now are studying blood samples obtained from patients with active tuberculosis and from subjects with differing racial susceptibilities, as well as from those who have received certain drugs which appear to increase TB susceptibility.

From all these studies it is hoped that a definite pattern of relationship between the factor and TB will emerge. This, coupled with further knowledge of chemical means of enhancing factor levels, may provide a valuable weapon against what is still America's ninth ranking cause of death. ########## jfa

"KIDS" COME IN ALL AGES AT

STANFORD MEDICAL CENTER

STANFORD. -- Most universities think of "kids" as young men and women at the 18 year old or "admissions" level; most of the rest of us use the term for what it is that wakes us on Sunday morning.

At the Stanford Medical Center they are interested in "kids" of all ages, stretching from shortly after birth to the oldest graduate student.

This wide range of interest has been brought into sharp focus with the move of the University's medical school and hospital from San Francisco to its new $22,000,000 Center on the campus.

The move brings the Center close to the Children's Health Council, the Stanford Convalescent Home, and a high concentration of skilled pediatricians in the Stanford area, to point up this change in thinking.

The work of these groups, a new pediatrics curriculum departure, and new blood in the pediatrics department all point toward the desire to attain the levels of new teaching, research and patient care necessary to meet the requirements of 1960.

The new curriculum departure involves the over-all plans for the Medical School: that of greater integration with the other departments of the University.

In addition, the new head of the Pediatrics Department, Dr. Norman Kretchmer from the N. Y. Hospital-Cornell Medical Center in N. Y. stresses still a different point of view for specific instruction in pediatrics.

NEW STANFORD HOSPITAL

FEATURES MODERN DIET KITCHEN

A modern kitchen where food is prepared under the supervision of expert dieticians will serve the new Palo Alto-Stanford Hospital.

All diets are specified in advance by physicians -- regular, bland, liquid, soft, or special -- and meals are brought to the patient's room by modern 'Meals on Wheels' food carts. Heated drawers in the carts, an advancement over the old hospital steam tables which once cluttered corridors at meal times, keep entrees at kitchen-hot temperatures. Salads, deserts, milk products, and other cold items are kept in refrigerated compartments.

Patients on a regular or unrestricted diet order from a daily menu which includes at least two entrees, vegetables, deserts, and choice of soup or broth. The cost of these meals is covered by normal Hospital charges, but patients may order a la carte items at nominal extra cost.

The large kitchen, which will also prepare food for the new hospital's cafeteria restaurant and the existing Palo Alto Hospital, is prepared to serve such special orders as breast of guinea hen under glass.

Head dietician for the Palo Alto-Stanford Hospital will be Mrs. Helen Anderson from Stanford-Lane Hospital in San Francisco; her assistant is Miss Ruth Cline of Palo Alto Hospital.

######## wh

"We will teach from the point of view of growth and development rather than that of disease," Kretchmer says. "To us the child is a growing organism with problems which arise from this fact; this must be seen apart from existing conceptions of kids with kids' diseases."

Dr. Kretchmer has brought new teachers and researchers to Stanford with him. They include Drs. Lewis Gluck and Sumner Yaffee, and biochemist Kenneth K. Tsuboi, Ph. D. They will assist in carrying out Kretchmer's new ideas.

The Children's Health Council and the Stanford Convalescent Home are only associated with the Medical Center, there are no direct organizational ties. Still, the facilities of each are used by the others, and the staffs and purposes all point the same way.

In addition, a joint pediatrics ward has been established in the new Palo Alto-Stanford Hospital which is a part of the Medical Center. It is the only such joint ward.

A committee of Medical School and private-practice pediatricians is the controlling body for ward policies.

The Children's Health Council is a day clinic which treats children from all walks of life, charging on an ability-to-pay basis. The Convalescent Home cares for chronically ill children requiring prolonged hospitalization.

Both these facilities are on Stanford-owned land, each less than a mile from the new Medical Center.

There is definitely growing interest in pediatrics as a medical specialty, and the intense concentration of both thinkers and doers in the Stanford area indicates that, if not already so, this area may soon become one of the great pediatrics centers of the world.

STANFORD MEDICAL SCHOOL CURRICULUM
CALLED "DISTINCTIVE, PROVOCATIVE"

STANFORD. -- The Stanford University School of Medicine curriculum, which will go into effect September 30 in the new $22,000,000 Medical Center, is described as "distinctive and provocative" in the current issue of the authoritative Journal of Medical Education.

The new Stanford plan is featured in an article, "Medical Education in the United States," by Dr. Richard H. Young, dean of the Northwestern University Medical School, and secretary of The Association of American Medical Colleges.

Says Doctor Young, in part:

"In several medical schools distinctive and provocative 'experiments' in medical education are being conducted. At Western Reserve, which has completed its sixth year of a new program, and at Stanford University, which will inaugurate a similar program this fall, basic science is taught according to subjects or areas of unified interest rather than along departmental lines.

"Laboratory work is carried out in small multidiscipline laboratories employing almost exclusively the experimental approach. Individual courses in anatomy, physiology, and biochemistry, among others, have given way to cooperative courses planned and executed by committees made up of representatives of the departments concerned.

"A highly integrated and correlated course presents the fundamental principles concerning the biological aspects of man in terms of normal structure and function.

- more -

Stanford Curriculum 2-2-2-2

"Other work of the first portion of the student's career deals with man as an individual and as a member of society. The psychological, sociological, economic and anthropological aspects of man are then examined, and the student is introduced to the patient-physician relationship. .....

"At Stanford, the total medical school program is 5 years, most of the students entering at the end of 3 years of college work. The basic medical sciences are spread out over the first 3 years.

"In addition to the time devoted to medical work, an amount of time equivalent to 1 academic year is distributed equally through the first 3 years and is devoted to non-medical work."

MEDICAL SCHOOL DEANS TO DEBATE

MODERN TRAINING OF PHYSICIANS

Where should a modern medical school be located and how are physicians of the future best trained?

These and similar questions are to be debated by the deans of the Bay Area's two medical schools on Tuesday evening (Sept. 15) at 8 o'clock over TV Station KTVU (Channel 2).

The major participants on the weekly Doctors News Conference program will be Dr. Robert H. Alway, dean of the Stanford University School of Medicine, and Dr. John B. deC. M. Saunders, dean of the University of California School of Medicine.

A third member of the physician panel will be Dr. Loren R. (Yank) Chandler, who served as dean of the Stanford school for 20 years, prior to his resignation in 1953.

This special program in the weekly series is designed to help mark the dedication on Thursday and Friday (Sept. 17 & 18) of the new $22,000,000 Stanford Medical Center, on the campus at Palo Alto.

Differences in the philosophy of medical education are represented by the two deans, as by their schools. Stanford is just completing the movement of its medical school from San Francisco to a closer integration with the rest of the university; U. C., on the other hand recently moved all its pre-medical and medical departments away from the Berkeley campus to its Medical Center in San Francisco.

The three physicians will face a newspaper panel made up of John F. Allen, San Francisco Examiner Science Editor, Jane Eshleman Conant, of the San Francisco News-Call Bulletin, and Jack Ryan, of the Oakland Tribune. ####jfa

STANFORD TO HONOR EMERITUS

TEACHERS AT CENTER DEDICATION

STANFORD. -- In the midst of dedicating their new campus quarters this week (Sept. 17 & 18), officials of the Stanford School of Medicine will pause to pay tribute to a 100-year-old tradition of great medical teaching.

Honored guests at a special party on Thursday evening will be some of the men and women who helped carry that tradition forward: the medical school's 46 living emeritus teachers.

Serving as hosts for the affair, which will be held at the University Club, on the campus, will be the Stanford Medical Alumni Association, made up in great part of hundreds of local practicing physicians who once were the eager students of their honored guests.

The party for the retired professors will be just one highlight of a two-day dedication ceremony marking the opening of the $22,000,000 Stanford Medical Center -- which includes not only the medical school, but two hospitals, a rehabilitation center, research laboratories and other facilities.

In contrasting the new building with the old tradition of great teachers, Dr. Robert H. Alway, medical school dean, reminded the alumni:

"This year Stanford starts its medical students in a new medical school in a new location with a new educational program and many new faculty.

- more -

"Under these circumstances, there is a risk of losing all carry over from the past -- all tradition. The Stanford medical school tradition most essential to perpetuate is the education of good doctors.

"The emeritus teachers you will honor contributed greatly to maintaining that tradition -- and we intend to do as well.

"We must remember that a doctor is 'good' in relation to his times and not in relation to any absolute standards. Stanford's many changes were predicated on making most likely the continued education of good doctors, looking to the future and society's attendant changes and needs."

Stanford medical school's history dates back just 100 years, because it was in May of 1859 that Dr. Samuel Elias Cooper welcomed the first class of students to his new school in San Francisco -- a school that was to be absorbed by Stanford in 1908.

As a further reminder of what Stanford owes to the past, oil portraits, busts and other momentoes of Doctor Cooper and those who followed him have been moved down from San Francisco to the new Center.

These, with appropriate placques, will be placed in various rooms and corridors of the new medical school in time for the dedication.

FOR RELEASE: WEDNESDAY, SEPT. 16 TELEPHONE DA 1-5310-11

$22,000,000 STANFORD MEDICAL CENTER
TO BE DEDICATED TOMORROW, FRIDAY

STANFORD, Sept. 16. -- Reports from a Nobel Prizewinner and the Federal Government's top research scientist will highlight dedication ceremonies of the $22,000,000 Stanford Medical Center here tomorrow and Friday.

Dr. Joshua Lederberg, Stanford professor of genetics and 1958 Nobel Laureate in medicine, and Dr. James M. Shannon, director of the National Institutes of Health, head a list of eleven nationally known scientists and laymen who will participate in the dedication.

Fifty thousand people are expected to visit the sprawling, 56-acre complex of three hospital and four medical school buildings during the two-day ceremony and a weekend of open house tours.

Other participants in the program, which will carry out the over-all theme of "Medical Care, the University and Society," will include William McPeak, vice-president of the Ford Foundation; Dr. Vernon Lippard, dean of the Yale Medical School; Dr. Lester Evans, executive associate of the Commonwealth Fund, and Dr. E. Cowles Andrus, of Johns Hopkins University.

Stanford Medical School scientists and teachers will present these reports on current research:

Doctor Lederberg on "Viruses as Genes," Dr. Norman Kretchmer, head of the Pediatrics Department, on "Heredity, Development and Disease," Dr. Arthur Kornberg, head of the Biochemistry Department, on "The Chemical Basis of Genetics," Dr. J. Garrott Allen, head of the department of Surgery, on

- more -

"Serum Hepatitis," Dr. Keith F. Killam, Jr., associate professor of pharmacology, on "Neuropharmacological Approaches to the Study of Drug Action," and Dr. Edmund H. Volkart, associate professor of sociology, on "Man, Disease and the Social Environment."

Concurrent with the speeches and research lectures, there will be seventeen scientific symposia during the two days -- round table discussions by Stanford and outside experts on every facet of human health. All will be open to the public.

The final ceremony will be the dedication proper on Friday evening at 8 o'clock in the open area before the spraying fountains which [illegible] dramatically mark the entrance to the new structure.

The major speech at this ceremony will be made by Frank Stanton, president of the Columbia Broadcasting System. Also listed as speakers are California Gov. Edmund G. Brown, Stanford President Wallace Sterling and Noel Porter, mayor of Palo Alto.

The whole program is designed to emphasize the paramount reason for moving Stanford's medical school from San Francisco to the campus: the geographical and intellectual integration of the school with the rest of the university, in an environment that will enable doctors of the future to be more capable of understanding and treating his patients as total persons.

The medical school, under Dr. Robert H. Alway, the dean, has revamped its curriculum into a five year program tailored to make the doctor himself a "whole" man. Continued teaching of the humanities and other non-medical subjects through the medical school years, integration of medical courses and independent research in extended free time will be emphasized.

STANFORD MEDICAL CENTER DEDICATION

SPEAKER ATTACKS DOCTOR ATTITUDES

STANFORD, Sept. 17. -- From the patient's point of view the modern doctor is too often an arrogant and selfish man who pretends to knowledge he doesn't have and is more concerned with his own bank account and convenience than with the health of those under his care.

Driven by the selfish manipulation of man's fear of death, modern medical research is badly out of balance and too much concerned with the quantity of lives saved instead of the "quality of living."

These two accusations were leveled at the medical profession here today by William McPeak, vice-president of The Ford Foundation, in a talk he labeled "The Small, Frantic Voice of the Patient," delivered as a feature of the Stanford Medical Center's formal dedication ceremony.

In underscoring his two major points, McPeak said:

"The major theme of my paper is that the voice of the typical patient in his own ultimate welfare is too little heeded in the practitioner's office and too strictly heeded in the research laboratory.

"In medical care the patient is not in a position to act as his own spokesman; in research he is not sufficiently competent or objective to do so.

"The weakness of the patient's voice, together with the correspondingly dominant voice of the doctor, can result on occasion in sub-standard medical care and certainly produces frequent dissatisfaction in the patient.

- more -

"In research, on the other hand, the patient and his family do have some voice. It is amplified by special disease organizations, by philanthropists, by government legislators and government agencies and swells into a vast chorus of dread and fear. It focusses on the disease that is dramatic, even though, like polio, it may not be widespread-- and on the big killers like heart disease and cancer."

In amplifying the "small, frantic voice of the patient," McPeak divided his accusations under three major headings:

1 - The doctor's "sense of personal convenience (and sometimes his profit)."

"Many doctors' offices reflect a disregard for patients through their inefficient management...the wastage of millions of hours of patient time...Such practices save the doctor little time or trouble, and therefore signify only his selfishness or his carelessness...

"...the difficulty of getting doctors to make house calls, especially at nights or weekends...too frequently real disasters occur as a result...

...unnecessary hospitalization...When the patient is hospitalized for days and given only a series of routine tests which might be given in the doctor's office, he suspects his physician of arranging things largely for his own convenience..."

2 - The doctor's attitude of knowing everything.

"...one of the attitudes on the part of doctors that pains and frustrates the patient is the one implied by his air of knowing all the answers...The most troublesome situation is in the instance of differential diagnoses, when one doctor says one thing is wrong and another with equal assurance says the opposite.

"...the patient is often at the mercy of the doctors and frequently follows one expensive and prolonged regime after another...everyone would be better if doctors would more often acknowledge that they don't know the answers.

DOCTOR ATTITUDES ATTACKED 3-3-3-3

"The extreme case is the liklihood that surgery is recommended when not necessary...the practical difficulty a patient encounters in getting second or consulting opinions."

3 - The personal attitude of the doctor toward his patient.

"...recent survey showed two-thirds of patients complained they missed the human warmth and personal responsibility of the old-time general practitioner .. What undoubtedly is involved is the personality change in the man who is becoming more and more the specialized scientist...a narrowing of the base for human contact..

"...welcome improvements in the attitude of organized medicine... American Medical Association and many medical societies are no longer the unenlightened trade unions and vested interests they once were...reform has resulted largely from the compromise necessary to exist and has not sprung basically from a concern for people as patients...

In order to redress the imbalance of medical research, McPeak said, "there is no need for a moratorium on research of any particular kind, but only a rational balance."

"Perhaps this means," he added, "first a balance between the rewards of research and the rewards of practice, so that those with lesser talent for research and greater talent for other pursuits will not be seduced into research activities of minimal and marginal promise.

"Secondly, I would ask a better balance between research concentrated on the killer diseases and that devoted...to such fields as psychiatry and psychosomatic medicine and all the various phenomena affecting one's sense of physical well-being, such as energy, fatigue, stress and rest. The refocus would aim to help many people stay well, in the fullest sense, instead of to help a few stay barely alive."

##########

IMPROVED CAMERA
AIDS HEART VICTIMS

for release upon receipt

Stanford Medical School radiologists have installed an improved X-ray motion picture camera in a laboratory in the new Medical Center on campus.

The apparatus films pictures studies of the heart in three dimensions.

Such studies are possible with the $100,000 device originally installed in the Stanford hospital located in San Francisco. The project was financed by a grant from the National Heart Institute of the U.S. Public Health Service and by private gifts.

A closed circuit television system has now been incorporated into the unit for use in the new Stanford Medical Center. This will permit a group of physicians in the room to follow the course of a catheter, or plastic tube, as it is inserted into the heart from an arm or leg vein. Remote viewing

- more -

by students and other physicians will also be possible.

"We can study cardiac motion and blood flow through the heart, lungs, and great vessels in two planes simultaneously," said Professor Herbert L. Abrams, Stanford radiologist in charge of the project.

"Conventional single-plane equipment give you only the height and width of a heart chamber. To study the chamber's motion and blood volume, you also need its depth, or third dimension.

"We can also 'stop' movement down to a thousandth of a second to get sharper views of pumping heart chambers and blood jets."

The perfected Stanford equipment employs 11-inch "image intensifiers" at right angles. One is sunk vertically into the floor beneath the patient, the other is mounted horizontally on rollers at his side.

Like the ordinary fluoroscopes, the electronic intensifiers form the X-ray picture on their circular 11-inch screens. Until recently, only 5-inch screens were available. The large screen permits study of the adult heart and pulmonary vessels at the same time.

The intensifiers make the fluoroscopic image 100 times brighter, thus lowering the amount of X-rays needed. This permits use of diagnostic motion picture techniques that give much

smaller X-ray dosage to patients than is possible when movies are made without intensifiers.

After a catheter has been inserted into the heart, an opaque substance is rapidly and automatically injected through the catheter into a heart chamber.

Meanwhile, X-ray tubes suspended from the ceiling beam their rays at right angles through the patient directly into the image intensifiers. The two images produced are photographed on 35 mm. motion picture film. Thus, movement of opaque material through the heart, lungs, and great vessels is recorded. In this way, actual events within the heart are depicted in motion, and may be viewed and re-viewed.

The end product is a double film strip showing the same motion from different angles. The two films can be studied or projected together to give dimensions of the cardiac chambers in two planes simultaneously.

In addition, two electronic "Dynapulse" devices are coupled to the apparatus. These further heighten picture intensity and permit very short exposure time. Essentially, these devices "store up" X-rays and release them in concentrated split-second burtts synchronized with the speed of the film through the camera. Film speed can be varied from six to forty-eight frames per second.

The 11-inch intensifiers were built in Holland and are the largest in use. A number of other single plane 11-inchers are being used in medical centers elsewhere, but Stan-

X-RAY 4/4/4/4/4/4

ford's is the first installation designed for simultaneous two-plane studies in the world.

The camera device is installed in the radiology department on the first floor of the Hospital in the newly-opened Medical Center

NEW $1,400,000 HEATING SYSTEM

TO SERVE STANFORD MEDICAL CENTER

A $1,400,000 steam heating system, under construction this summer on the Stanford campus, will provide heat for the new Stanford Medical Center in the fall.

The plant, which will also serve other Stanford classroom and administration buildings, is being constructed near the western terminus of Serra Street on the campus proper. Four boilers delivering 160,000 pounds of steam pressure an hour will be installed and the building erected around them.

6500 feet of buried trunk line is being installed below campus streets.

A special line will be constructed from the plant to the location of the new Medical Center and the Palo Alto-Stanford Hospital on the northern end of the campus.

for release upon receipt

STANFORD'S NEW MED CENTER ---
BEAUTIFUL BUT FUNCTIONAL

The ultra-modern and "very functional" medical center opening this fall on the Stanford University campus may well be an architectural masterpiece.

Designed by an internationally renowned architect, Edward D. Stone -- who also conceived the American Embassy at New Delhi and the U. S. Pavilion at the Brussel's Fair -- the multimillion dollar, fifty-six acre complex includes three hospital and four medical school buildings. A total of sixteen acres of floor space is included in the Center which may be enlarged or modified depending upon the future demands of medical science.

Admittedly inspired by Stanford's traditional rectangular "Main Quadrangle," Stone patterned the new Center along the same lines. It is of similar height -- three stories -- and in the shape of an irregular letter "H" interconnected by a single red-pebbled roof. The architect felt that the three story height of the new group was both practical and economical. A feeling of

- more -

harmony with the rest of the Campus is also the result.

Similarly, the avenue of approach and the open park in front of the original Stanford Quadrangle has been incorporated into the planning of the Medical Center which it approximates in size. Like the majestic Palm Drive access to the Campus, the public approach to the Center from Willow Road will be tree-lined and formal, although in a natural setting.

"I tried to retain the spirit and principle of the old quadrangle without slavishly copying that which was neither practical nor economically justifiable," Stone says.

"There are many historical examples of institutions such as Oxford, Cambridge, and Harvard where unity and harmony has been achieved although the buildings which have been built over several hundreds of years, and the culture and taste of each successive period reflected in the architecture. The creative resourcefulness of each successive epoch was not curbed, but the skill of each designer in turn, resulted in a building harmonious with its predecessors."

The old "Quad" is built of massive sandstone blocks and pitched roofs. The Medical "Quad" is structured with reinforced concrete, with concrete columns and horizontal floor slabs.

To relieve what would be the monotony of poured concrete, the walls and columns of the Medical Center are patterned, simulating the varied surface effect provided by the old Quadrangle's

rough hewn stone work.

A flat roof extends outward on all sides to provide needed shade in what is an unusually sunny area. It also compensates visually for the lack of an expensive pitched roof and costly tiles.

Perforated cloister-like grillwork repeats the pattern to be found on the walls and columns. Grills serve to screen passageways between the seven buildings making up the complex and recall Stanford's richly ornamented Victorian-Romanesque campus a stone's throw away. All buildings are nearly the same height and like their sandstone counterparts surround planted and flowering courtyards which has the effect of unifying the Medical Center group.

Actually, much of the architecture of the main section of the Campus is hinted at in the Medical Center. It might be said to be a contemporary version of Stanford's adaptation of Romanesque which was brought to California by the Spaniards. The Catholic missions in the West are typical of this style, which at Stanford, features red tile-roofed buildings of long and low design, flanked by protective arches built on an imposing scale.

The Center's Plan

The seven separate yet interconnected buildings comprising the Farm's new "H" shaped Medical Center are set within an area

approximately 680 by 640 feet.

Beyond Governor's Square directly in front of the ediface and within the lower aperture of the Center's "H" shaped plan, is an 88 by 154 foot reflecting pool containing fountains. Behind the pool is the Clinic Building which houses most of Stanford's clinics. To the left, extending eastward, are the three buildings which make up the Palo Alto-Stanford Hospital. At the right is the Rehabilitation Building, behind which--and also extending eastward -- are the Library and the Medical Sciences Buildings which contain the main facilities of the Stanford University School of Medicine.

To the casual observer, the Medical Center appears to be a large, three-story building. Actually it contains five floor levels (ground, first, second, third and penthouse), measuring approximately 12 1/2 feet vertically from floor to floor. The first story is at grade level, and the roofline is approximately 40 feet above the ground.

Allied Fields Neighbors

"Stratification"

The new Center is designed so that related medical facilities are generally on the same floor level. For example, the Palo Alto-Stanford Hospital's third floor contains obstetrics, gynecology, and pediatrics, all related fields of medicine.

On the third floor of the clinic building, next to the hospital, are the Stanford outpatient clinics for pediatrics and obstetrics-gynecology. Here, also, are the Stanford School of Medicine's pediatrics and obstetrics-gynecology departmental offices.

On the same level of the nearby library building -- easily accessible by means of a covered walkway connecting the two buildings -- is the child psychiatry outpatient clinic.

This general pattern is followed throughout the new Center. Surgery, cardiology, neurology, physical therapy, pathology services, the Hospital's clinical and chemical laboratories and Medical School teaching laboratories, for example, are in several connecting buildings, but all on what is known as the second floor "stratum" of the Center.

Flexibility of Design

In planning the Center, a great many factors entered into determination of the final design. A key factor, however, was flexibility, necessary in a rapidly-changing field such as medicine in order to allow for changes in the assignment of space and ease of future physical modification. Also, because the Medical Center is being built in stages -- the overall design is so arranged that future buildings may be added in an orderly and practical sequence.

MED CENTER DESIGN
6-6-6-6-6-6-6-6-6

Use of a 22 foot square horizontal module in the Medical Center's design provided, for example, standard dimensions of various corridors and rooms as well as placement of doors and windows. Adoption of this module also gave the architect considerable latitude in adapting parts of buildings to particular needs. Thus, decisions concerning future additions to the Center are simplified: planners are able to regard the structures and their component parts as "building blocks" of known sizes.

Also, steel-reinforced concrete construction of floor and ceiling slabs allowed the architect to dispense with a labyrinth of interior load-bearing walls and the clutter of inside vertical supports. Except for certain basic interior load-bearing walls, the inside vertical supports are placed only at 22 foot square intervals at the corners of the "module" mentioned above. Thus, in reality, the great majority of interior walls are well-insulated partitions which can be quickly and economically removed -- next month of thirty years hence -- to make way for virtually any desired modification of interior space.

UNIQUE 'DIAL-A-TUBE' SYSTEM
INSTALLED AT NEW STANFORD HOSPITAL

Rapid transit within the walls of the new Palo Alto-Stanford Hospital is implemented by a unique device that puts the famed pneumatic tube mail system of Paris in the aboriginal category.

Swift movement of records, drugs, reports, specimens, and other small items between buildings and departments is assured by a modern and versatile pneumatic tube system that features direct dialing of other departments.

Each tube station is equipped with a telephone dialing device which enables a nurse to direct the course of the cylinder to any other part of the hospital by simply dialing a number.

This modern form of communication greatly speeds up normal hospital operations. The results of a blood test can be in a doctor's hands at a patient's bedside a few seconds after its completion in the laboratory, or a drug can be transmitted from the Hospital Pharmacy to any other Hospital location in less than a minute.

FOR FURTHER INFORMATION CONTACT:

CHRONOLOGICAL HISTORY OF

STANFORD MEDICAL SCHOOL

1858 -- First medical school on the Pacific Coast founded in San Francisco by Dr. Samuel Elias Cooper; academically chartered as the Medical Department of the University of the Pacific. The parent university, established at Santa Clara in 1851, moved in 1871 to San Jose, and from there to Stockton in 1921, where it is now known as the College of the Pacific.

May 1859 -- Formal opening ceremonies of school held in Musical Hall, San Francisco; 13 students matriculated.

Sept. 13, 1859 -- M. D. degree conferred on two candidates who, before coming to San Francisco, had completed a full course of medical lectures elsewhere.

Oct. 13, 1862 -- Death of Dr. Cooper (1822-1862)

Autumn 1864 -- Faculty suspended operations and several (including Dr. Levi Cooper Lane, nephew of Dr. Cooper, and Dr. Henry Gibbons Sr.) joined faculty of new medical school begun then in San Francisco by Dr. H. H. Toland.

1870 -- Dr. Lane and his close associates resigned from the Toland Medical College. With members of Cooper's earlier faculty, they reorganized the Medical Department of the University of the Pacific, in which all but one of the Toland students then enrolled.

1872 -- Faculty of the Medical Department of the University of the Pacific severed connections with that university and became the medical department of the University (City) College, an institution founded 12 years earlier in San Francisco. The medical department was known formally as the Medical College of the Pacific.

HISTORY
2-2-2-2

Nov. 6, 1877 -- M. D. degree conferred on Alice Higgins, the first woman physician to be graduated from the school.

October 1882 -- Faculty of the Medical College of the Pacific severed connections with the University (City) College and, with its faculty and students intact, became Cooper Medical College. The new school was founded by Dr. Lane for this purpose at the corner of Sacramento and Webster Streets in San Francisco. (This building has been in continuous use as a medical school for 77 years, the last students having left the premises in the summer of 1959)

1892 -- Additions to the medical college building by Dr. Lane.

1893 -- New hospital erected by Dr. Lane at Clay and Webster Streets, adjacent to medical school. He proposed to name the building the Pauline Lane Hospital, after his wife; but she preferred that it be called, simply, the Lane Hospital.

1895 -- Lane Hospital Training School for Nurses established, later to become the Stanford School of Nursing.

Feb. 9, 1902 -- Death of Dr. Lane (1830-1902).

Jan. 1, 1908 -- Cooper Medical College, its properties and equipment granted to Leland Stanford Junior University, at that time a very young university (instruction began at Stanford in October, 1891). In accepting the gift, the university proposed to "carry forward the aims and ideals of Cooper Medical College and to increase and extend the facilities and opportunities for medical education." President of Stanford at that time was Dr. David Starr Jordan (1851-1931).

Sept. 8, 1909 -- Instruction in medicine at the Medical Department of Leland Stanford Junior University formally inaugurated, with Stanford's Professor John M. Stillman as acting Departmental executive. Dr. Henry Gibbons Jr. remained as Dean of the Cooper Medical College faculty, which continued medical instruction until 1912, when the last of its students was graduated.

Jan. 1, 1911 -- Dr. Ray Lyman Wilbur (1875-1949) became Dean of the Medical Department faculty.

HISTORY
3-3-3-3

November 1912 -- Dedication and formal opening of Levi Cooper Lane Library of Medicine and Surgery, an outstanding collection of more than 30,000 volumes and 10,000 pamphlets. Then, as now, the Lane Library was regarded as the finest medical collection west of Chicago.

Oct. 22, 1913 -- John Casper Branner (1850-1922) became Stanford's president, as Dr. Jordan became University Chancellor.

Jan. 22, 1916 -- Dr. Wilbur became university president, after Dr. Branner's retirement. Dr. William Ophüls (1871-1933) followed as Dean of the Medical faculty.

December 1917 -- Formal opening of new Stanford Hospital which was built adjacent to medical school in San Francisco.

March 1922 -- Formal opening of Nursing Building opposite Stanford-Lane Hospital.

April 1933 -- Death of Dr. Ophüls; succeeded as Dean of the Medical faculty by Dr. Loren Roscoe "Yank" Chandler.

Sept. 1, 1943 -- Dr. Donald B. Tresidder (1894-1948) became fourth president of Stanford. Dr. Wilbur, retired as president and named Chancellor in 1941, had served as acting president in the interim.

April 5, 1949 -- Dr. J. E. Wallace Sterling became president of Stanford, following Dr. Tresidder's death in 1948,

July 1953 -- Stanford's Board of Trustees made decision to move medical school from San Francisco to university campus near Palo Alto, where new buildings were to be constructed. President of the Board at this time was Lloyd W. Dinkelspiel (1899-1959).

September 1953 -- Dr. Windsor Cooper Cutting named Dean, following resignation of Dr. Chandler.

Summer 1955 -- Architect Edward D. Stone, F.A.I.A., began work on new Stanford Medical Center.

August 1956 -- Fund-raising Public Campaign for the Medical Center announced by the Hon. Herbert Hoover. Campaign chairman was W. Parmer Fuller III of San Francisco.

March 1957 -- Dr. Robert H. Alway, Professor of Pediatrics, named Acting Dean, following resignation of Dr. Cutting.

June 1957 -- First construction activity begun for Stanford Medical Center, with excavation for Palo Alto-Stanford Hospital.

July 1957 -- Rehabilitation Building construction begun.

February 1958 -- Dr. Alway named permanent Dean.

During August 1959 -- Palo Alto-Stanford Hospital to begin admitting patients.

Sept. 17-18, 1959 -- Dedication and formal opening of Stanford Medical Center: the Stanford School of Medicine, Palo Alto-Stanford Hospital, and the Stanford Clinics.

Sept. 21, 1959 -- First classes begin in new Medical School buildings.

Two Stanford faculty members and one student will take part in a day-long conference on care for the aged tomorrow (WEDNESDAY) at Rickey's Studio Inn in Palo Alto.

The meeting is for operators and staff members of ~~XXX~~ nursing homes and institutions for the aged. It is sponsored jointly by the State Department of Public Health and the Peninsula Nursing Homes Association.

Dr. William H. Northway, professor of physical medicine at Stanford, will speak during the morning on the topic, "The Oldster." During the afternoon there will be a panel on "Helping the Aged—WhoDoes What?" Two of the panelists will be Leona McGann, assistant professor of preventive medicine, and physical therapy student Barbara Kent.
and Barbara Kent, a student physical therapist.

RELEASE ON RECEIPT

STANFORD TO LAUNCH ALL-OUT

ATTACK ON SKIN DISEASE

STANFORD, Calif.--A Stanford Medical Center research team representing many scientific specialties is launching an all-out attack on psoriasis, the disfiguring skin disease which affects 3 to 4 million Americans.

At present, the cause of the ailment is completely unknown, although psychological, hereditary and allergic factors may be involved. Current treatment is on a trial-and-error basis and therapeutic measures have not been improved significantly in several decades, according to Dr. Eugene Farber of Stanford.

The unusual, multi-discipline attack is made possible by a generous grant to Stanford of $295,928 from The John A. Hartford Foundation, Inc., of New York City. The award was announced today by Mr. Ralph W. Burger, President of the Foundation.

The Hartford Foundation was originally established by John A. Hartford to distribute his personal charitable donations. He left it the bulk of his estate; and his brother, George L. Hartford, who died in 1957, left his entire estate to the Foundation. John A. Hartford was president of the Great Atlantic & Pacific Tea Company, and George L. Hartford was chairman of the board.

--more--

See Psoriasis

Dr. Robert H. Alway, medical school dean, said the investigation will be under the direction of Dr. Farber, Professor of Dermatology. The grant is for a three year period.

Psoriasis is a chronic disease characterized by the eruption of round red patches covered by unsightly white scales--chiefly on the elbows, knees, scalp and back. It has been estimated that it affects as much as 2 per cent of the world's population.

The sores frequently recur and for this reason the disease is very discouraging for those who suffer from it. Doctors presently can only soothe the sores with ointments and salves, but are not able to cure the illness.

The research program is unusual for its use of the facilities and skills of numerous medical school departments and their investigators.

Doctor Farber's associates in the investigation will include Dr. Alvin J. Cox, head of the Department of Pathology; Dr. William H. Northway, director of the Division of Physical Therapy; Dr. Harold M. Schneidman, Assistant Clinical Professor in Dermatology; Dr. Anthony P. Moreci, physiologist; Dr. Victor Wheatley, chemist, and Dr. Joseph B. Peterson and Dr. Muhammed Aswaq.

Fields to be covered include chemistry, pathology, genetics, immunology, physiology, rheumatology, pediatrics, dietetics and psychiatry:

1 - Chemistry: Gas chromatography and other chemical methods will be used to study the chemical reactions of psoriasis in its active state and when it is improving.

2 - Pathology: A newly established laboratory of skin pathology will utilize latest techniques for analysis of patients' skin.

3 - Genetics: Since there is evidence that the tendency toward psoriasis may be inherited, studies will be made of common traits among victims with similar genetic backgrounds.

--more--

4 - Immunology: There is some evidence that allergic processes are involved in the disease, so this aspect will be studied by immunologists.

5 - Physiology: Skin blood flow in psoriatic patients and their responses to environmental temperatures and humidity will be investigated.

6 - Rheumatology: Experts in the field of rheumatoid arthritis will study the significance of the fact that 6 per cent of patients with arthritis also have psoriasis.

7 - Pediatrics: Child specialists trained in dermatology will study the differences between youngsters with the disease and their normal brothers and sisters.

8 - Dietetics: Since a sudden gain in weight or a disproportionate amount of fat in the diet may cause outbreaks of psoriasis, a careful survey of patients' eating habits will be made.

9 - Psychiatry: An explanation will be sought of the fact that psoriasis may spread during a period of emotional stress.

In addition the Stanford researchers plan to investigate the natural history of the disease, to conduct a re-evaluation of currently used drugs and to study other related factors.

The research team hopes its efforts will stimulate similar work in other laboratories. The group will provide or exchange information as quickly as it is available.

SWITCHBOARD DONATED TO

STANFORD PHYSICAL THERAPY

Old switchboards never die -- and they don't just fade away either.

At least not as long as there are groups like the Stanford Physical Therapy corps around.

The newest piece of equipment in the new $22 million Stanford Medical Center is a 25-year-old telephone company switchboard recently donated to the physical therapy unit's pre-vocational training room. Mr. Roy Maloney, Palo Alto manager of the Pacific Telephone Company, made the presentation.

The detail and accuracy needed to run a switchboard make it a valuable tool in restoring coordination lost as the result of illness or accident. The pre-vocational unit will use the instrument for testing and evaluation.

The unit's function is the evaluation of a referred patient's skills and abilities despite whatever disability he might have.

Wallace McDonald, pre-vocational supervisor, reports that telephones will be connected to the board, and in the future a recording device will also be added to it.

Evidently switchboards are pretty hard to come by -- ones not functioning, at least. Maloney looked for two months before he discovered a PBX that could be donated to the unit. "This board," he said, "finally turned up in San Leandro -- it was the only one we could find that wasn't in use or about to be put to such."

Stanford Medical Center
News Bureau Palo Alto, California

FOR RELEASE: On Receipt TELEPHONE DA 1-5310-11

STANFORD, Calif.--Dr. James F. Jenness is now hearing things better than he has for years, thanks to an assist this fall from his alma mater.

Dr. Jenness, a retired Methodist minister, is 92 years old. Almost 70 years ago he moved west from Boston and became a member of the pioneer first graduating class of Stanford University. Only three members of the 32 in that class are alive today. The University first granted diplomas in 1892.

Dr. Jenness has had trouble hearing for about 15 years. He received some help from a hearing aid, but it gradually did him less and less good.

This summer he wrote Prof. Hayes A. Newby of Stanford's Speech Pathology and Audiology Division, asking for assistance. He had noticed in the papers that Dr. Newby was director of a workshop at Stanford Medical Center on problems of the hard of hearing.

Dr. Newby arranged some tests and decided that a binaural system, with an aid for each ear, would serve Dr. Jenness best. Dr. Jenness is suffering from a nerve-type hearing loss due primarily to age, Dr. Newby said. Late last month he fitted Dr. Jenness with the devices.

"It's quite an improvement," Dr. Jenness said that day, although he admitted some things didn't sound quite natural to him yet. Later on his wife, Beulah, reported he was "getting on to it." Her husband "is very, very deaf," she said. "Anything that helps is good." She finds it much easier to talk to him with the new aids.

The hearing aids for Dr. Jenness' use were loaned to Stanford by the Zenith Radio Corporation.

--more--

Dr. Newby pointed out that while the Speech Pathology and Audiology Division does not provide a hearing aid advisory service for the general public, an exception was made in this instance to assist an early alumnus.

Dr. Jenness did undergraduate work at Boston University before coming to Stanford. Both he and his brother, Charles, who is now dead, graduated in 1892. Later Dr. Jenness was graduated from Iliff Theological School in Denver, then received a Ph.D. in theology from Boston University.

He was pastor of the First Methodist Church of Palo Alto from 1901 to 1903. Mrs. Jenness still remembers that University Avenue in Palo Alto was a dusty street until it was oiled during their stay in the city.

After leaving Palo Alto Dr. Jenness was a minister in Argentina, Chile and Panama. He returned to Palo Alto in 1932 when he retired. The couple now lives at 342 Oxford Ave., in the house they built when they moved here.

One of their two sons is still living. He is Arthur F. Jenness, head of the psychology department at Williams College, Williamstown, Mass. They have four grandchildren.

STANFORD PROFESSOR WINS RESEARCH PRIZE

Dr. Alan K. Done, assistant professor of pediatrics at Stanford University School of Medicine, has won the 1959 $1,000 Ross Laboratories Award for Pediatric Research from the Western Society for Pediatric Research.

He received the prize and a plaque at the society's annual meeting in Santa Monica last week. He was honored for his basic research in toxicology and endocrinology.

He has studied the effects of drugs, especially aspirin, on metabolism. Metabolism is the chemical process by which organisms produce energy and materials necessary for life processes.

His interests in endocrinology have centered mostly on the metabolism of adrenal hormones in children.

Dr. Done joined the Stanford faculty in September, 1958. He formerly taught and did research at the University of Utah, where he received his A.B. and M.D. degrees.

He lives at 907 Bainbridge Ct., Sunnyvale, with his wife and four children.

ADMISSIONS TO BE REDUCED DURING HOSPITAL MOVE

Nonemergency admissions to Palo Alto-Stanford Hospital Center will be stopped from Nov. 24 to Dec. 2 to free staff and equipment for the big move out of the old Palo Alto Hospital, hospital administrator E. Dwight Barnett announced today.

Emergency care, including services for maternity patients, will continue without disruption during the move, Dr. Barnett said.

Departments in the old hospital will move to the new buildings in Stanford Medical Center during Thanksgiving Week. The new unit will be in full operation at 6 a.m. Nov. 30. Emergency and maternity patients will be admitted to the old hospital prior to that time.

Dr. Barnett said that the move has been planned to take advantage of the normal drop in admissions which occurs during a holiday period. In addition, Midpeninsula physicians and Stanford faculty members have been directed not to admit elective cases in surgery, medicine, gynecology or pediatrics.

Final details of the hospital shift are being worked out and will be announced later this week, Dr. Barnett said.

INFECTIOUS DISEASES PLAN ESTABLISHED IN NEW HOSPITAL

The opening of the new Stanford Medical Center provides an unusual opportunity to put into practice certain well-established and widely accepted principles for the prevention, control and study of infectious diseases which occur in hospitals all over the world. These principles are not new. However, the details have been modified to fit the demands of modern hospital construction and medical practice.

The program affects each and every phase of hospital activity and therefore requires the full cooperation of every member of the hospital community as well as the patients and the patients' visitors. The chain of prevention and control is only as strong as its weakest link. Constant self-discipline and close supervision are the prices demanded for an effective program of this nature.

The program is as follows:

1) A hospital infection control committee was established. Known as the Infectious Diseases Advisory Committee, it includes ~~three~~ ~~four~~ representatives of the physicians practicing in the community, ~~three~~ ~~four~~ members of the faculty of the Stanford University School of Medicine, and a representative from the administration of the Palo Alto-Stanford Hospital Center. The committee advises the hospital administration and the entire medical center's personnel on matters relating to infectious diseases.

2) Dr. Lowell A. Rantz, Stanford professor of medicine and associate dean for clinical and postgraduate affairs, has been appointed hospital epidemiologist. He sees that recommendations from the committee are put into action. He is assisted by faculty members in pediatrics, surgery and obstetrics where problems are unique to their specialties.

News Bureau Palo Alto, California

FOR RELEASE: TELEPHONE DA 1-5310-11

NOTE TO CITY EDITORS, SCIENCE REPORTERS, RADIO-TV EDITORS, ET AL:

There will be a press conference Nov. 17, 1959, at 10:30 a.m. at the Stanford Medical Center to demonstrate and explain procedures used in the Palo Alto-Stanford Hospitals to control infections. The story is for release Thursday, Nov. 19, 1959.

Time Magazine reported last month that "Surgeons rated hospital infection as the most pressing problem aired" at the recent meeting of the American College of Surgeons. Hospital-acquired infections are a major problem all over the world, in fact. Staphylococci, especially, are a growing cause of infections in newborn infants and in surgical patients; many of these are due to "staph" that are resistant to commonly used antibiotics. Hospitals have become breeding places for serious infections because most hospitals harbor resistant staph.

Stanford Medical Center is setting up a comprehensive program directed at prevention and control of this problem. A reporter and photographer from your organization are invited to see at first hand what a thorough program involves in a new hospital. Sampling techniques, used on all hospital personnel and in every hospital room or patient area, will be shown. Sanitary procedures for housekeeping, dietary and nursing departments will be demonstrated or explained. Visits are planned to a specially equipped isolation room and an operating room.

Typical of the startling findings already turned up are: (1) It only takes half an hour for a newly introduced virulent bacteria to spread throughout a whole hospital floor--if proper isolation techniques are not used; (2) a surprisingly high percentage of doctors and nurses carry in their noses or on their hands staph which can cause infections.

Please let us know if you plan to send a reporter and/or photographer. A simple lunch will be served after the briefing session (at approximately 12:30). The conference will be in room W256 on the second floor of the Palo Alto wing of the hospitals (see enclosed map--the Palo Alto wing is the west pavilion on the map).

3) An informational and educational program has been under way for the last two months. It is directed at the professional staffs (private physicians and faculty members), nurses, the resident staff, medical and nursing students, paramedical and service personnel. A movie on proper techniques has been shown to 1,600 persons; there have been four mailings of rules and policy statements; and lectures and demonstrations have been given to various departments. The aim has been to instill in each individual working at the center a sense of responsibility for the prevention of infectious disease, and to demonstrate proper techniques.

4) A comprehensive and detailed plan for isolating patients with communicable diseases or those especially susceptible to them is being put into operation. Fourteen isolation rooms are being readied and other rooms can be put into use if necessary.

5) Modifications in equipment and techniques have been put into use for housekeeping, laundry and other service departments.

6) The ventilating system is now being improved to curb the spread of disease.

7) Several construction changes have been undertaken, particularly the installation of double doors on isolation rooms and addition of ultraviolet light equipment in operating and delivery rooms.

8) Restrictions have been placed on the use of some antimicrobial agents to insure an effective reserve of potent agents for use against antimicrobial-resistant infections.

9) A comprehensive system of case-finding has been set up for detection and control of certain infections. In practice, this means that attending physicians are obligated to take cultures from and report cases of infection. The epidemiologist may also detect cases on his own and he or his representative make daily rounds of the hospital to see whether any new cases may have

--more--

occurred.

10) A far-reaching epidemiological survey of the hospital facilities and personnel has been started to detect and evaluate the initial incidence and magnitude of the staphylococcal problem. It is designed to dovetail with an extensive research project on wound infections, infections of newborn infants, and similar problems common to all major medical centers.

FOR RELEASE: on receipt TELEPHONE DA 1-5310-11

CLINICS BUILDING OPENING FOR FIRST TIME

The Boswell Building at Stanford Medical Center will open for care of clinic patients for the first time Monday morning, Dr. Andrew Hunt announced today.

Dr. Hunt is in charge of the outpatient clinics, where services are provided by faculty and students of the Stanford University School of Medicine. Since this summer all clinics have been in the adjacent Edwards Building.

Patients should report first to the reception desk on the first floor of Boswell, Dr. Hunt said. Each will then be sent to the proper clinic from there.

Medicine, surgery and dermatology clinics will move to Boswell Monday. Obstetrics, pediatrics and eye clinics are to stay in Edwards temporarily. They will move into Boswell later when the remainder of the building is finished.

Orthopedics, neurology and ear-nose-throat services will also stay in Edwards, where they will be located permanently.

Dr. Hunt said that opening of part of the facilities in Boswell provides room for expansion needed with the steady growth of the clinic patient load.

The Boswell Building makes up the crossbar of the H-shaped center. It is located directly behind the pool at the front of the center.

###

(Nov. 20, 1959)

Stanford Medical Center
News Bureau Palo Alto, California

FOR RELEASE: on receipt TELEPHONE DA 1-5310-11

Services at Palo Alto Hospital, headquarters for first class medical care on the Midpeninsula since 1931, will be suspended the first week of December, Administrator E. Dwight Barnett announced today.

Beginning Tuesday (NOV. 24) personnel will start preparing for the big move from the old hospital to the new Palo Alto-Stanford Hospital in Stanford Medical Center. The following day rented trucks will begin hauling equipment to the new building.

The move will be accomplished without interruption in care of acutely ill persons, Dr. Barnett said. Emergency services will be available at all times.

At 6 a.m. Monday, Nov. 30, all admissions, including emergency and maternity cases, will be to the new hospital. Officials of Palo Alto-Stanford Hospital Center, who direct operations of both units, expect that all patients will be out of the old building by about Wednesday, Dec. 2.

The board of governors of the hospital center is studying proposals for use of the old building. A committee of the Palo Alto Medical Staff has recommended that it be used for a psychiatric care unit and for overflow when there are more patients than the new 434-bed hospital can handle.

Palo Alto Hospital has about 180 beds in the permanent parts of the building, although its capacity has been 303 beds because of overcrowding and temporary buildings attached to the structure.

The administration plans to refurbish the old building and to repair some of the equipment before opening it up again.

When patients are out of the building, it will mark the first break in service there in 28 years.

--more--

Plans for the move have taken several weeks to prepare. They are under the general direction of Associate Administrator David Starkweather.

In all, 243 beds in the old hospital will be closed down. Sixty have already been closed. One hundred and eleven beds are now open in the new hospital. When the move is completed 372 will be in operation in the new unit. Other nursing stations will be opened as the patient load increases, Starkweather said.

Midpeninsula physicians have been asked not to admit patients for non-emergency care starting Nov. 24. Patients will again be admitted for elective care the afternoon of Dec. 2. Combined with the reduced patient load normally coming over Thanksgiving, this action will free hospital personnel and equipment so the move can be carried out.

The fewest beds planned to be available during the move is 263. However, if a disaster were to occur locally more beds could be opened promptly, Starkweather said. In that case, nurses and other personnel would have to postpone some of the moving chores to care for patients.

Starkweather estimates that approximately 90 patients will actually have to be moved from the old hospital to the new one by ambulance. This shift is scheduled Saturday and Sunday, Nov. 28 and 29. There will be no charge to patients for the ambulance service.

In addition, tons of supplies and equipment will have to be moved. They include everything from tiny needles and ampules of medicine to giant lights from surgery or the $200,000 worth of drugs in the hospital pharmacy.

--more--

Maternity patients will stay in the old building, however, until they are dismissed. The only exception might be in the case of a mother who required a longer than usual hospital stay. No patient will be transported, though, if his or her doctor considers the move at all dangerous for the patient.

In accordance with the policy of the hospital center's board of governors, the slightly higher rates in effect for the rooms in the new hospital will be charged patients when they are moved into their new quarters.

Because some maternity and emergency patients will have to stay in the old building past the transfer hour of 6 a.m. Nov. 30, the center will actually have two staffs in maternity, surgery, and all the departments which support these services as long as they are needed.

The move is expected to take eight days. Elective admissions will be restricted for five days in advance of the actual transfer and for three days afterward to allow the staff to ready the new quarters.

(NOTE TO EDITORS: If you are interested in taking photographs of the move, the best time to photograph equipment would be Wednesday, Nov. 25. Patients will not be moved until Saturday, Nov. 28.)

(Mailed Nov. 20, 1959)

Stanford Medical Center

FOR RELEASE: on receipt TELEPHONE DA 1-5310-11

DEPUTY ADMINISTRATOR NAMED FOR HOSPITAL CENTER

Oliver E. Deehan, an associate administrator of Palo Alto-Stanford Hospital Center since August, 1957, has been promoted to deputy administrator.

Dr. E. Dwight Barnett, administrator of the hospital center, announced the change today.

Deehan's promotion is part of an administrative reorganization designed to free Dr. Barnett of day-to-day matters and to leave him more time for work at the policy and planning levels. Until now there has been no deputy administrator on the staff.

Other changes include transfer of certain departmental responsibilities among Barnett's five assistants. In addition to Deehan, they include three associate administrators, Miss Virginia Brown, David Starkweather and Lowell Smith, and an assistant administrator, William Moir, who supervises business affairs of the center. Starkweather and Smith were previously assistant administrators.

Deehan has full responsibility for implementing current policies of the administration. He is also in charge of personnel and in-service training. Staff members report directly to Dr. Barnett, however, when seeking policy changes or when planning new policies.

Deehan, 32, received his B.S. degree from Columbia University in 1955 and his M.S. degree in hospital administration from Columbia's School of Public Health and Administrative Medicine in 1957.

He is married and has three children, Ellen, 5, Robert, 4, and Carol, 2. The family lives at 226 Solana Dr., Los Altos.

FOR RELEASE: on receipt TELEPHONE DA 1-5310-11

EMERGENCY SERVICES IN PALO ALTO

TO MOVE TO NEW HOSPITAL MONDAY

The emergency room at the new Palo Alto-Stanford Hospital will open for the first time at 6 a.m., Monday (NOV. 30), Administrator E. Dwight Barnett reminded local residents today.

The emergency room at the old Palo Alto Hospital will close at the same time, Dr. Barnett said. All patients requiring emergency treatment should come or be brought to the new hospital after that time.

The entrance to the emergency room is off a special road on the El Camino Real side of the Stanford Medical Center. The hospital can be reached off of Willow or Quarry Roads on the Stanford side of El Camino Real.

All admissions, including maternity cases, will be to the new hospital beginning at 6 a.m. Monday. Expectant mothers should go to the old hospital before that time.

Nonemergency admissions have been stopped this week to free staff and equipment for the move to the new hospital.

FOR RELEASE: upon receipt TELEPHONE DA 1-5310-11

EXPERIENCED ADMINISTRATOR NAMED TO HOSPITAL STAFF

Paul Fleming, an administrator with many years of experience, has been named to a temporary post on the staff of Palo Alto-Stanford Medical Center, it was announced today.

Fleming will serve as an assistant to Dr. E. Dwight Barnett, administrator of the center. Dr. Barnett said that for the next few months Fleming will concentrate on planning for reopening the Palo Alto Hospital, which has been closed since early December.

Recently Fleming has been a hospital consultant in the San Francisco area. He was graduated from Stanford in 1932 and later worked at two hospitals in the Bay Area.

He was assistant manager of Mills Memorial Hospital in San Mateo from 1935 to 1940 and was administrator of Hahnemann Hospital in San Francisco from 1940 to 1944.

Fleming has also served as assistant director of New Haven (Conn.) Hospital, which is associated with Yale Medical School, and as director of Huntington Hospital on Long Island, N.Y.

Fleming, 50, is the son of Mrs. Caroline H. Fleming of 1139 University Ave., Palo Alto. He is married and has one daughter, although he and his wife are separated. For the time being he is living in a hotel in Palo Alto.

STANFORD MEDICAL ALUMNI ASSOCIATION ELECTS OFFICERS

Three California physicians have been named officers of the Stanford Medical Alumni Association for 1960, it was announced today.

The Association, made up of graduates of Stanford University's School of Medicine, also chose five new members of the Board of Governors.

Each new official, his year of graduation from the medical school, and his address are listed below. Each is holding an Association post for the first time unless otherwise noted.

President, Dr. Clifford B. Cherry, '35, 2400 Beverly Blvd., Los Angeles.

Vice President, Dr. G. B. Robson, '34, 2410 Clay St., San Francisco. Dr. Robson was on the Board of Governors from 1951 to 1953 and was vice president in 1954.

Secretary-Treasurer, Dr. William R. Grannis, '44, Medical Plaza, Pasteur Dr. and Welch Road, Palo Alto. Dr. Grannis is also on the Board of Governors. His term began this year and expires in 1961.

The following were elected to the Board of Governors for a three year term (1960-62):

Dr. John A. Azevedo, '23, 22146 Prospect St., Hayward.

Dr. John M. Baker, '44, 616 Alhambra Blvd., Sacramento.

Dr. Marshall J. Fiese, '44, Fresno State College, Fresno.

Dr. Louis L. Huff, '36, 5033 Southridge Ave., Los Angeles. Dr. Huff was vice president in 1958 and on the Board of Governors the three years before that.

Dr. Joseph F. Walsh, '42, 3117 "G" Street, Eureka.

THREE STANFORD FACULTY MEMBERS HONORED BY NEW YORK ACADEMY OF SCIENCES

Three members of the faculty of the Stanford University School of Medicine were recently elected fellows of the New York Academy of Sciences.

Honored by the Academy were Dr. Ronald Grant, professor of physiology; Dr. George A. Feigen, associate professor of physiology; and Dr. Carlton E. Schwerdt, associate professor of medical microbiology.

In announcing the fellows' election, an Academy spokesman said that a fellowship is a distinguished honor which is conferred upon a limited number of its members for outstanding work toward the advancement of science.

Dr. Grant was honored for his work in neurophysiology, or the functioning of nerves and brain. He is director of a Stanford research program in neurophysiology established in 1958.

Dr. Feigen was also cited for research in physiology. He has studied the physical and chemical factors that determine the effectiveness of blood substitutes used in shock, the adaptation of the circulatory system to high altitude and the process whereby isolated tissues, such as the heart, liberate histamine during allergic attacks. He is presently director of several research programs in physiological immunity.

Dr. Schwerdt is noted for his research on animal viruses. He has studied the physical and chemical characteristics and the crystallization of polio virus. He discovered that the polio virus really has two fractions--or parts--one of which causes polio, one of which does not.

The scientists will receive engraved certificates indicating their election to fellowship in the Academy. Professor Grant lives in Portola Valley while the other two men live in Palo Alto.

ROCKEFELLER FOUNDATION MAKES $3,000,000 GRANT TO STANFORD MEDICAL SCHOOL

The Rockefeller Foundation has made a $3,000,000 grant to Stanford University toward the development of its School of Medicine, Stanford President Wallace Sterling announced today.

Two-thirds of the total is to be used over the 10-year period beginning Jan. 1, 1960, "to strengthen work in the basic sciences." Dean Robert H. Alway of the medical school said that the $2,000,000 will help raise some current faculty salaries as well as provide funds for additional faculty to reinforce the basic medical sciences.

The remaining $1,000,000 is to be an allocation toward construction of a clinical sciences research building. In order to receive this share of the grant, however, the University must have cash, securities or firm pledges for an additional $3,000,000 for the building. Current estimates are that the building will cost at least $4,000,000.

The second part of the Rockefeller grant means that the University has reduced to $6,000,000 the amount needed to finish the first stage of development at Stanford Medical Center. The University is currently seeking $3,000,000 to complete payment on the recently opened $21,000,000 complex, in addition to the balance sought for the clinical research building.

The new grant is the second largest ever made to the medical school. The largest was $3,100,000 from the Ford Foundation in 1957 for endowment for faculty salaries.

--more--

Just this fall Stanford moved the school from San Francisco to its new campus medical center. The medical curriculum has been drastically changed to increase student understanding of the inter-relationship of the medical sciences and to teach the social as well as the physical aspects of medicine.

"We are most grateful for the generosity of the Rockefeller Foundation," Dr. Alway said. "The grant will help us reinforce the most important part of any medical school--the faculty. It also gives us a start on financing the completion of the first stage of the Stanford Medical Center."

The clinical sciences research building was in the original program for the Medical Center, but construction was deferred until additional funds became available. The Medical Center includes the clinic and hospital facilities of Palo Alto-Stanford Hospital Center and the Stanford University School of Medicine.

The new building will provide research facilities for the school's departments of medicine, surgery and others concerned with patient care. It will be located between the Stanford hospital pavilion and the Medical School Building on the campus side of the center complex.

Some of the research facilities for the clinical departments are now located in the Boswell Building. However, Boswell was designed primarily for patient services.

There is no target date for completion of the research structure, although the Rockefeller Foundation specified the $1,000,000 must be put to use before Dec. 31, 1969.

NOTE TO EDITORS: Announcement of the grant will be made at the kickoff luncheon of the 1960 March of Dimes drive in Santa Clara County, noon Wednesday at the St. Claire Hotel in San Jose. Release time was specified by March of Dimes officials.

MARCH OF DIMES GRANT MADE TO STANFORD MEDICAL SCHOOL

The Stanford University School of Medicine has received a $141,722 grant from The National Foundation to support teaching of methods of comprehensive care for the rehabilitation of patients afflicted by chronic disease and disability.

The program will include education of students in medicine, nursing, physical therapy, speech therapy, occupational therapy, social work and vocational counseling.

The grant was announced jointly today by J. E. Wallace Sterling, president of Stanford, and Basil O'Connor, president of The National Foundation. It is part of $1,500,000 being allocated by The National Foundation to 14 medical schools in the country for education in the health professions. The grant is effective Jan. 1, 1960.

It is the largest National Foundation grant ever made to Stanford, according to Bert L. Legg, 1960 Santa Clara County March of Dimes Chairman. The announcement was made in conjunction with the kickoff of the 1960 campaign in the county.

"Nothing is more vital to the future welfare of the disabled than for doctors to have full knowledge of modern rehabilitation techniques," Dr. Sterling said. "Tomorrow's major medical problem will be long-term, crippling diseases. We hope, through this March of Dimes grant, to help prepare tomorrow's doctors and other associated medical personnel to meet those problems."

Mr. O'Connor said that The National Foundation has been supporting pilot studies for teaching rehabilitation in medical schools since 1950. "From our experience with polio patients," Mr. O'Connor said, "we realized that when crippling or chronic disability occur, rehabilitation is a fundamental part of good medical care rather than something to be added after all else has failed.

"The battle for health is now primarily a battle against the cripplers. The National Foundation's immediate objectives are birth defects and arthritis, in addition to polio. But what is learned in such studies as are now being carried out at Stanford goes far beyond the boundary of any single disease. Our aim is to find the best means of training disease fighters for tomorrow."

The new March of Dimes grant brings to over $330,000 the support for rehabilitation teaching at Stanford given by The National Foundation. The grant is under the direction of Dr. Robert H. Alway, dean of the medical school. Coordinator of the program will be Dr. Rodney Beard, executive head of the Department of Preventive Medicine and director of the Stanford Rehabilitation Services.

"Our goal is to help the patient attain the maximum degree of physical, social, vocational and psychological adjustment to his illness or disability," Dr. Alway stated.

Medical students, nurses, physical therapists and speech therapists are already enrolled at Stanford. Occupational therapists, social workers and vocational counselors from nearby colleges and universities will take part in the program while they are getting field experience.

EMERITUS NURSING DIRECTOR TO BE HONORED

Miss Enid Hutchinson, director of nurses at Palo Alto Hospital for 28 years until her retirement this summer, will be honored by her former associates at a dinner Tuesday night (DEC. 15).

Between 150 and 200 persons are expected to attend the dinner, at which Miss Hutchinson will receive a citation signifying that she has been named first nursing director emeritus.

In addition to the citation, she will also receive a gift from the Palo Alto Medical Staff, according to Dr. E. Dwight Barnett, hospital administrator.

Dr. Barnett is administrator of Palo Alto-Stanford Hospital Center, which operates the Palo Alto Hospital as well as the new Palo Alto-Stanford Hospital in Stanford Medical Center. Palo Alto Hospital is closed temporarily while the building is being refurbished. It is expected to open again in a few months.

The dinner will begin at 8 p.m. at Rickey's Studio Inn. Attending will be hospital department heads, officers of the Palo Alto Medical Staff, representatives from the board of hospital directors and the hospital administration, and other invited guests.

The dinner is part of the Christmas program for hospital employees, which also includes departmental parties. The program is being paid for by income from the vending machines in the hospital center and by a contribution from the private doctors who make up the Palo Alto Medical Staff.

Miss Hutchinson now lives in Mt. Hermon, near Santa Cruz.

NURSES SHORTAGE HITS PALO ALTO-STANFORD HOSPITAL CENTER

Palo Alto-Stanford Hospital Center is unable to care for all the patients seeking hospitalization locally because of a shortage of qualified nurses, Administrator E. Dwight Barnett said today.

"We could open another nursing station right now and provide an additional 32 beds if we only had the personnel," Dr. Barnett said.

Emergency patients are not being turned away, he said. However, doctors with patients needing elective surgery or medical treatment have not been able to have them admitted.

Dr. Barnett commented that one nursing unit could be filled with patients now and another about the first of the year--if nurses were available. "I want the community to know that it is not a shortage of facilities that is keeping patients out of the hospital," Dr. Barnett said.

The new Palo Alto-Stanford Hospital has a total of 434 beds, of which 372 are now open. Just last week the hospital swung into full-scale operation and Palo Alto Hospital was closed. The old hospital, which will be refurbished in the next few months, housed up to 305 patients but was built for about 180 patients.

The hospital also needs licensed vocational nurses and nurses aides, although the stations could be staffed if enough registered nurses were on hand.

The administrator explained that a quick expansion of services is chiefly responsible for the shortage, since there has been no chance to build up personnel gradually. Last year the hospital anticipated reaching a patient load equivalent to 120,000 patient days annually by April, 1960. That figure has already been reached now.

The administration is attempting to find suitable personnel throughout the country, but Dr. Barnett predicted that the shortage would last at least until January, when the many nurses who are students' wives return to the area.

DR. ARTHUR KORNBERG LEAVES TO RECEIVE NOBEL AWARD

Dr. Arthur Kornberg, professor and executive head of the Department of Biochemistry at Stanford University School of Medicine, is en route today to Stockholm, Sweden, where he will receive the 1959 Nobel Prize for Medicine.

He shares the award with Dr. Severo Ochoa of New York University. The men were honored for manufacturing nucleic acids in the laboratory. Nucleic acids are key substances in living cells. Their work is expected to have an important influence on research into cancer, viruses and heredity.

All the Nobel Prizes, including those for chemistry, physics, literature and an outstanding contribution to peace, will be presented Dec. 10 at the Stockholm Concert Hall. The presentations will be followed by a banquet at the City Hall.

The next day Dr. Kornberg will deliver a technical address on his work to the members of the Caroline Institute, which annually chooses the winner of the prize for medicine or physiology.

The night of Dec. 11 the King and Queen of Sweden will fete the winners with a banquet at the Royal Palace.

Dr. Kornberg's wife, Sylvy (cq), and their three sons are accompanying him to Europe. They left San Francisco by plane Wednesday night (DEC. 2). Mrs. Kornberg has been co-author of research articles with her husband.

They will spend this weekend in London, then fly to Stockholm Monday (DEC. 7). They will stay in Sweden until Dec. 15, and then will go to Copenhagen, Denmark. They plan a vacation on the continent before returning to the United States late in December.

PEDIATRICS GROUP TO MEET AT STANFORD MEDICAL CENTER

Approximately 150 pediatricians will gather at Stanford Medical Center Sunday (DEC. 6) for the annual meeting of the Northern California Chapter of the American Academy of Pediatrics.

Dr. Joseph H. Davis of Palo Alto is local chairman for the event. Also working on arrangements is Dr. Saul J. Robinson of San Francisco, chairman of the chapter's Scientific and Educational Committee.

In the morning there will be a panel discussion on "The Pediatrician Faces Juvenile Delinquency," followed by a business meeting.

Panel participants include Dr. Arthur Carfagni, psychiatrist with the San Mateo County Probation Department; Irving Kriegsfeld, executive director of the Mission Neighborhood Center in San Francisco; and Dr. Eli M. Bower, research coordinator for the California State Department of Education.

Moderator will be Dr. Herbert Korngold, a pediatrician practicing in Sacramento, chairman of the chapter's Committee on Juvenile Delinquency.

In the afternoon five members of the faculty of the Department of Pediatrics of Stanford University School of Medicine will discuss some of the newer advances in the field.

Speakers will include Prof. Norman Kretchmer, head of the department, Associate Prof. Luigi Luzzatti, and Instructors Norman Sissman, Louis Gluck and Sumner Yaffee.

Following the afternoon session there will be tours of Stanford Medical Center, the Children's Health Council and the Stanford Convalescent Home.

STANFORD PHYSIOLOGIST RECEIVES CITATION

Dr. Jefferson M. Crismon (cq), professor and executive head of the Department of Physiology at Stanford University School of Medicine, today received a special citation from the American Heart Association for "distinguished service to research."

The citation was presented at a meeting of the association's board of directors in New York City.

Citations were given to 15 leaders in medical teaching and research who have completed full five-year terms on the AHA Research Committee or who served as chairmen of the committee.

Dr. Crismon was a member of the committee from 1952 to 1957 and was chairman in 1956-57. The committee supervises allocations for fellowships and research grants from the association.

Dr. Crismon, 51, has been on the Stanford faculty since 1937. During 1957-58 he was a Guggenheim Fellow and worked at the Medical Research Council Laboratory in London, England.

He was named head of the physiology department in 1951. He is widely known for his research on cold injury and other effects of low body temperature.

He is married and has two children. The family lives at 1805 Guinda St., Palo Alto.

HOSPITAL TO CONDUCT TOURS FOR EXPECTANT MOTHERS

Palo Alto-Stanford Hospital Center will begin holding regular tours for expectant mothers next month, it was announced today.

Tours will be held the first and third Wednesdays of each month, beginning Feb. 3. They will start at 11 a.m. from the information desk in the main hospital lobby and will last approximately one hour.

Tour groups will be limited to 10 persons. Mothers-to-be may call DA 1-1200, extension 5311, to sign up. Women with the earliest delivery dates will be given priority.

The groups will be limited to expectant mothers unless fewer than 10 persons sign up. If less than 10 are listed, a woman's husband or mother may join the tour.

The guide will be Miss Alice Denhard, assistant professor of nursing (obstetrics) in the Stanford University School of Nursing.

Miss Denhard will explain the admitting procedure and show women where the emergency room is in case they need to enter the hospital that way.

She will also show them the entrance to the labor room area, the husbands' waiting room, nurseries, and the mothers' accomodations.

EXPLANATION OFFERED FOR BLOOD CLOT MYSTERY

CARMEL--Two Stanford University faculty members working at San Mateo County Hospital have discovered a possible explanation for a mystery that has plagued medicine for years.

The mystery is this: Why do blood clots formed in the legs often break off and flow elsewhere in the body, seriously endangering the lives of patients, while those formed in the arms do not?

Such clots are potentially dangerous for all patients who are confined to bed. When they break off they can flow to the lungs and block the blood supply to part of that vital organ. The result can be serious damage to part of a lung, heart failure, or even death of the patient.

An explanation was offered here yesterday by Dr. Edward Rubenstein and Dr. Arthur R. Lack of San Mateo in a paper presented at the annual meeting of the Western Section of the American Federation for Clinical Research.

Dr. Rubenstein is clinical instructor in medicine at Stanford's School of Medicine. Dr. Lack is clinical instructor in pathology.

The researchers have discovered that the temperature of the blood flowing through the veins near the surface of the lower leg of a bedridden patient averaged 12 degrees Fahrenheit lower than the 98.6 degrees usually called "normal."

Further studies showed that clots formed at this low temperature are much more fragile than those formed at 98 degrees. Apparently this is so because complete formation is slowed down.

--more--

These fragile clots are probably more likely to break off and flow elsewhere in the body where they can cause serious or fatal damage, Dr. Rubenstein said.

There is always a tendency for blood to clot when it stops flowing. Low temperature favors this because cool blood is thicker. The reduced circulation of a bedridden patient contributes to the effect.

Physicians are well aware of the fact that clots are frequently formed in the arms as well as the legs. Some blood smapling methods will stop circulation and cause them, and they occur in some patients being given solutions intravenously.

"But why are the leg veins so notorious?" Dr. Rubenstein asks.

"Once a clot forms at low temperature," he said, "there is clear evidence now that it is less cohesive. It won't stick to itself or the vein wall as well and is likely to be dislodged."

The arms are considerably warmer than the legs, he said. In addition, the arms tend to stay warmer because they are usually more active then a bedridden patient's legs. When clots are formed they do not break off. Eventually they are dissolved by a normal body mechanism involving chemicals in the blood.

What can doctors do to reduce the likelihood that fragile clots will form in the legs? Dr. Rubenstein suggests that more research is needed to answer that question.

He would suggest studying the possible effects of having the patients wear socks or use more blankets, both in bed and during operations. In surgery, he said, doctors usually don't worry about the patient's legs and they may be uncovered for a long time.

The doctors' report was based on an investigation of 20 normal and 20 bed-confined subjects.

RESEARCH POSSIBILITIES IN PERU SUGGESTED

CARMEL--Scientists trying to learn more about the causes of some of the diseases which cripple and kill civilized Americans--especially heart ailments--might do well to study the less highly civilized natives of the Peruvian highlands.

That suggestion came today from a Stanford University School of Medicine heart specialist who spent a month in Peru last year examining research possibilities in the Peruvian Andes.

Dr. Herbert Hultgren, associate professor of medicine at Stanford, delivered a paper on medical problems in Peru at the annual meeting of the Western Association of Physicians. Co-author of the paper is Dr. Warren Spickard, associate clinical professor of medicine at the University of Washington School of Medicine.

The investigations were supported by grants from the United States Public Health Service and the Sonoma County Heart Association.

"Many of the interesting medical phenomena observed in the Peruvian Andes undoubtedly will provide important clues to the basic mechanisms of diseases seen in our sea level society," Dr. Hultgren says.

Certain types of heart and circulatory ailments are extremely rare, the physicians report. These include high blood pressure, coronary artery disease, and hardening and thickening of arteries.

--more--

Hard work and diet may play a role in reducing the incidence of these ailments, Hultgren and Spickard said. The natives not only do a lot of manual labor; they also have to breathe more air to get the necessary oxygen. Their food is high in carbohydrates and vegetable proteins, but their fat intake is not known precisely.

The Peruvian way of life has its medical disadvantages, however. There is a high incidence of gallstones and of disease of the biliary tract, which carries bile from the liver to the intestine. Following major surgery, though, the blood clots commonly arising in veins of American patients and which can cause lung damage, heart failure or death, seldom occur.

Normal adults and children in the area have certain physical characteristics which would be considered as signs of heart disease if the people lived at sea level. The lungs are large and the right side of the heart is enlarged.

And for visitors climate can be hazardous unless they allow time to get accustomed to the high altitude. "Soroche, or acute mountain sickness, is noticed by nearly everyone who travels from Lima (near the Pacific Ocean) to La Oroya (12,225 feet) for the first time," the authors note.

Symptoms include weakness, labored breathing, headaches, loss of appetite and occasional other discomfort. A few people do not get used to the altitude and may lose weight and suffer from severe insomnia.

That suggestion came today from a Stanford University School of Medicine heart specialist who spent a month in Peru last year examining research possibilities in the Peruvian Andes.

Dr. Herbert Hultgren, associate professor of medicine at Stanford, delivered a paper on medical problems in Peru at the annual meeting of the Western Association of Physicians. Co-author of the paper is Dr. Warren Spickard, associate clinical professor of medicine at the University of Washington School of Medicine.

Insert from P.2

Use B 96A

~~Heart disease is extremely rare, the physicians report, as is atherosclerosis, the deposit of fatty substances in arteries which can lead to hardening of the arteries. So are diabetes and high blood pressure.~~

Hard work and diet may play a role in reducing the incidence of these ailments, Hultgren and Spickard said. The natives not only do a lot of manual labor; they also have to breathe more air to get the necessary oxygen. Their food is high in carbohydrates and vegetable proteins, but their fat intake is not known precisely

STANFORD ANATOMIST RECEIVES ANTHROPOLOGICAL AWARD

Dr. William W. Greulich, executive head of the Department of Anatomy at Stanford University School of Medicine, has been named winner of the 1960 Viking Fund medal and award for "outstanding achievement in physical anthropology."

Dr. Greulich is widely known for his studies of the growth and development of children. He has documented the retardations among Japanese youngsters who survived the atom bombs dropped on Hiroshima and Nagasaki. He has also examined children to study differences in development among different races.

Previous winners of the award include such internationally recognized anthropologists as Henry M. Vallois, director of the Museum of Man in Paris, France; Raymond Dart, discoverer of many important human fossils in South Africa; and Sir Wilfred LeGros Clark of the University of Oxford, England, who helped expose the notorious Piltdown forgery.

The medal and a $1,000 prize will be presented to Dr. Greulich at a dinner in New York during March. He is the first American to receive the award since 1957.

Dr. Greulich was selected for the award by a committee from the American Association of Physical Anthropologists. The award is sponsored by the Wenner-Gren Foundation for Anthropological Research, New York, N.Y.

Dr. Greulich received degrees from Kenyon College and the University of Denver before winning his Ph.D. at Stanford in 1934. He has been on the Stanford faculty since 1944. He lives at 1 Clayton Dr., Menlo Park.

FIRST OPEN HEART SURGERY PERFORMED AT STANFORD MEDICAL CENTER

Stanford University surgeons have performed the first open heart operation at the new Palo Alto-Stanford Hospital in Stanford Medical Center.

The operating rooms were opened in the new hospital early in December. Stanford's School of Medicine moved to the campus last fall from San Francisco.

The patient, a 36-year-old Sacramento salesman, is in good condition today, physicians said. He is eating well and can sit up in bed. He is expected to be walking around by the end of the week.

The operation was performed last Friday. It lasted for 5½ hours. For one of those hours the patient was kept alive by a heart-lung machine which maintained circulation for him while his heart was open.

The patient suffered from an atrial septal defect--a hole in the wall which separates the right and left upper chambers of the heart, or atria. Because of the defect he was short of breath and grew tired easily, symptoms which grew worse as he grew older. The surgeons stitched the hole closed.

The doctors also knew before the operation that a vein leading into the heart from the right lung was emptying into the wrong chamber. During surgery they discovered a second vein also emptied into the wrong atrium. They said that they put stitching into the heart wall to make a barrier so the blood flowed into the proper chamber.

A septal defect is one of many types of heart disease which can now be treated by open heart surgery. Head of the Stanford team is Dr. Norman Shumway, assistant professor of surgery.

STANFORD CLINICS RESUME SERVICES

FOR STUTTERERS, HARD OF HEARING

PALO ALTO--The Stanford University Speech and Hearing Clinic next week will resume group therapy sessions for adult stutterers and group instruction in lip reading for adults who are hard of hearing.

Both programs are run throughout the year except during academic vacation periods, according to Dr. Virgil A. Anderson, director of the clinic.

Sessions for the stutterers will be held Monday nights from 7:30 to 9:00, beginning January 11th. Lip reading classes are scheduled Mondays from 8:00 to 9:00 p.m., starting January 11th.

The clinic is located in Edwards Building of the Stanford Medical Center, 300 Pasteur Drive, Palo Alto. Fees are nominal--$10 for the quarter.

All interested persons are invited to attend, Dr. Anderson said. The program allows for some individual therapy if needed.

Dr. Robert J. Duffy is staff advisor for the stutterers, and Ray Lage is the clinical assistant in immediate charge of the program. The lip reading class is under the supervision of Miss M. Jo Eeckhout (cq); Miss Margaret Meeker is the therapist who teaches the class.

Further information may be obtained by calling the clinic at DAvenport 1-1200, extension 5416.

UNIQUE ISOTOPE DETECTING DEVICE INSTALLED AT STANFORD MEDICAL CENTER

A unique electronic device which should open up new areas for nuclear research and speed development of better diagnostic techniques using radioactive isotopes has been installed at Stanford Medical Center.

The instrument was specially designed and built for the Isotope Division of the Stanford University School of Medicine. While there are other devices for detecting minute amounts of radioactivity in a patient's body, the new one at Stanford has many more uses and is more precise than previously available ones.

Researchers hope that it will assist them in developing improved methods of diagnosing diseases of the thyroid, liver, kidney, blood-forming organs and brain. It should also be useful in tumor and cancer detection.

It will also be used to train medical students and doctors in latest techniques in the field of nuclear medicine. Dr. Joseph P. Kriss, director of the Isotope Laboratory, will supervise operation of the instrument. It is available for treatment of both private and teaching patients at Palo Alto-Stanford Hospital Center.

Following a two-year survey of nuclear medical equipment manufacturers, Dr. Kriss and Dr. Robert Loevinger, consulting physicist for the Isotope Laboratory, selected Atomation (cq), Inc., Division of C. W. Reed Company, Inc., to build the highly specialized instrument. Atomation, Inc., is located in Los Angeles.

It is called a Dual Detector Tri-D Scanner because of its unique ability to automatically scan in three dimensions and because of its two complete detection channels which can function independently or in combination. The scanner is expected to be marketed for about $20,000.

--more--

The instrument detects and automatically records gamma rays (X-rays) given off by radioactive isotopes which have been injected into a patient. Different chemical substances tend to be concentrated in different parts of the body, and a study of the location of materials which have been "tagged" with a radioactive isotope may help locate and define the size or function of certain organs and certain tumors.

The amount of radioactive material used is very minute, according to Dr. Kriss. It is too small to be detected by chemical means. Commonly used isotopes include those of iodine, iron, gold, copper, arsenic and chromium.

The flexibility of the device makes it unusual, Dr. Kriss said. With the two detecting and recording channels, it can detect radioactivity from two parts of the body at once or simultaneously measure the uptake of two different isotopes in the same area.

It can also detect positrons, or positively charged particles with the same mass and size charge as negative electrons. Positrons are spotted by placing the two detectors so that they face each other.

Positrons are detected when they disintegrate, because they produce gamma rays which come off in exactly opposite directions. Only those rays which enter the two detectors simultaneously are counted "in coincidence." Other rays which are scattered from a distance or which come from other isotopes do not reach the detectors "in coincidence" and are not counted. This arrangement helps appreciably in exact localization. Some tumors of the brain tend to concentrate positron-emittors, such as arsenic.

The instrument scans an area automatically and records its findings so they are available for later study. Scanning can be done either horizontally or vertically.

Funds for purchasing the scanner came from the Atomic Energy Commission, the Palo Alto-Stanford Hospital Center and an anonymous donor to Stanford University.

STANFORD MEDICAL CENTER NEWS BUREAU
Palo Alto, California

FOR FURTHER INFORMATION CONTACT: Samuel Moffat, DAvenport 1-1200, Ext. 5311

FILE COPY

NOTICE TO ALL CITY DESKS, NEWS DESKS, ETC.

Effective at 8 a.m., Saturday February 6, 1960, your reporters should call the Emergency Room at Palo Alto-Stanford Hospital for information about patients brought to the hospital for emergency treatment. The number to call is DA 1-1200, extension 5142.

The Nursing Office, which had previously handled all reporters' calls about patients, will now have reports on hospitalized patients only. The number for the Nursing Office is DA 1-1200, extension 5181. During the night when the nursing supervisor is making her rounds, the switchboard operator will page the supervisor for you if you need information about a hospitalized patient.

In the past the Emergency Room has not had a large enough staff to care for patients and answer your calls properly too. However, the nurses are now prepared to take the calls. This system will be instituted to make Emergency Room reports available sooner. We hope it will work satisfactorily for you.

Extra copies of this notice are enclosed for you to distribute to your reporters.

STANFORD CLINICS' FACILITIES OPENED TO ELIGIBLE COUNTY PATIENTS

Palo Alto-Stanford Hospital Center and the County of Santa Clara have signed an agreement to permit certain north county residents to get treatment at the Stanford Clinics in Palo Alto instead of having to go to the County Hospital in San Jose, it was announced today.

The announcement was made jointly by Dr. F. George Gillick, director of medical institutions for the County of Santa Clara, and Dr. Andrew Hunt, director of ambulatory services for the Stanford Clinics.

Patients living in Palo Alto, Los Altos or Mountain View are considered north county residents by the County.

Only patients certified as eligible by the Medical Social Service Department at the County Hospital will be offered care under the program.

The County will pay the Hospital Center a fee for each patient visit, the fee to cover all services rendered. Services will include doctor's care, laboratory tests, X-rays and drugs.

Patients will be required to present written evidence of eligibility except in emergency cases.

County officials said that the agreement was signed because enough facilities are not available for clinic care in San Jose, and because it is difficult for many patients to get to San Jose.

It is not known yet just how many patients will be assigned to the Stanford Clinics, but Dr. Gillick said that only "a small number" is expected to be served. ###

PALO ALTO-STANFORD HOSPITAL CENTER APPOINTS NEW ASSOCIATE ADMINISTRATOR

Walter Rentschler, who served as an administrative resident at Palo Alto Hospital in 1958-59, has been named an associate administrator of Palo Alto-Stanford Hospital Center, Administrator E. Dwight Barnett announced today.

From last June until March Rentschler was assistant administrator of Reid Memorial Hospital in Richmond, Indiana. He has an M.S. degree in hospital administration from Columbia University and an A.B. from Gettysburg (Pa.) College.

He was an officer in the U.S. Air Force from 1954 to 1957.

His major responsibility in his new post will be supervising professional services for hospitalized patients. He began work March 14.

Rentschler is married and has a one-year-old son. The family lives at 1865 Ednamary Way, Mountain View.

200 SKIN SPECIALISTS EXPECTED AT STANFORD MEETING

Approximately 200 skin specialists from four western states are expected to attend a scientific meeting under the auspices of the San Francisco Dermatologic Society at Stanford Medical Center this Saturday. The meeting marks the establishment of the Stanford Dermatology Research Laboratories.

The principal speaker for the meeting will be Dr. Stephen Rothman, Professor of Dermatology at the University of Chicago. Dr. Rothman, an internationally recognized specialist, is best known for his original research on the chemistry and physiology of skin disease.

Dr. Rothman's topic will be "Basic Research in Dermatology: Present and Future."

There will also be a morning program on psoriasis, a disfiguring skin disease, by four members of the Stanford dermatology research staff. Speakers will be Dr. Eve Reaven, Dr. Anthony P. Moreci, Dr. Victor R. Wheatley and Dr. Muhammed Aswaq.

In the afternoon there will be a discussion of patients with specific skin diseases by Dr. Rothman, Dr. Alvin J. Cox, Head of the Department of Pathology at Stanford University School of Medicine and visiting dermatologists.

The chairman for the meeting will be Dr. George T. Wilson of Palo Alto.

The Division of Dermatology at the Medical School recently received a $295,928.00 grant from the John A. Hartford Foundation for a multi-disciplined study of psoriasis.

STANFORD FACULTY MEMBER NAMED MARKLE SCHOLAR IN MEDICAL SCIENCE

Dr. J. Thomas August, instructor in medicine at Stanford University School of Medicine, has been appointed a Markle Scholar in Medical Science, it was announced today.

The appointment includes a $30,000 grant which will be paid to the medical school over a period of five years to support Dr. August and to aid his research.

Dr. August is one of 25 young medical scientists in the United States and Canada selected for the scholarship program by the John and Mary R. Markle Foundation of New York. He was the only northern California faculty member chosen.

The Foundation has made grants annually since 1948 to relieve the shortage of faculty members in medical schools and to strengthen medical education.

The Stanford scholar is 32 years old. He received his A.B. degree from Stanford in 1951 and his M.D. four years later. He is married to the former Jean Nordstrom (Stanford '51) and they have two children, Christina, 3, and Paul, 1. The family lives at 500 Melville Ave., Palo Alto.

After interning at Los Angeles County General Hospital for a year, Dr. August served as resident house physician to Sir Stanley Davidson at the Royal Infirmary, University of Edinburgh, Scotland, in 1955-56.

He held posts at Beth Israel Hospital and Peter Bent Brigham Hospital in Boston and at the Harvard Medical School before coming to Stanford last year.

His research interests include studies of the endocrine glands and their secretions, and metabolism. His outside interests are reading, international affairs, skiing and hiking.

EMERITUS PROFESSOR TO SUPERVISE LIBRARY COLLECTION

Dr. Arthur L. Bloomfield, emeritus professor of medicine at the Stanford University School of Medicine, has been appointed director of the historical collection at Lane Medical Library, Librarian Clara S. Manson announced today.

Dr. Bloomfield retired in 1954 as head of the department of medicine after 26 years of teaching at Stanford. He now lives in San Francisco. He is one of the University's most distinguished physicians and revered teachers.

Lane Medical Library is the largest medical library west of Chicago and one of the nation's finest medical school libraries. Formerly located in San Francisco, it was moved to the University campus last summer when Stanford Medical Center opened.

Since his retirement, Dr. Bloomfield has been preparing a major work, A Bibliography of Internal Medicine: Communicable Diseases. When the first volume was published in 1958 the National Library of Medicine News hailed it as "one of those rare items which one does not hesitate to call a classic."

"Dr. Bloomfield has brought to his task the kind of wisdom which only a dean of the profession could master," the review continued. "The book is, as well, a tribute to the soundness of the collections of the Stanford Medical Library, on which it has been based."

Volume two was published last month. Both volumes were issued by the University of Chicago Press.

Dr. Bloomfield replaced Professor C. D. O'Malley, who resigned as director of the historical collection last year after holding the post 11 years.

In his new post Dr. Bloomfield will direct selection of volumes to be added to the historical collection.

EYE DISEASE RESEARCH TOOL AT STANFORD MEDICAL CENTER

Stanford University surgeons are using a beam of light five times as intense as sunlight to explore new frontiers in the treatment of eye diseases, the Division of Ophthalmology announced today.

The beam comes from a $13,500 Zeiss light coagulator purchased with part of a $51,000 grant from the National Institutes of Health. The investigators are Dr. Milton Flocks, assistant clinical professor of surgery (ophthalmology), and Dr. H. Christian Zweng, clinical instructor in surgery (ophthalmology).

There are only a few of the light coagulators in use in the United States, the researchers report, and they are used almost entirely for treatment, particularly in cases of retinal detachment. Two of them are located in San Francisco at the University of California Medical Center and at Children's Hospital.

The Stanford grant is the only one made so far for research into new uses of the machine. It will finance three years of research.

The coagulator produces an intense beam which can be focused to a point. Light comes from a xenon tube and is so strong it is only left on for a fraction of a second when aimed at an eye. The beam is aimed with a shield in the way to reduce intensity. The shield is removed momentarily during treatment.

Because the light will pass through transparent tissue and liquid, the beam has been used to treat defects at the back of the eye. For example, the intense light will burn out a tumor on the retina, the light-sensitive coating that lines the rear of the eye.

--more--

The beam has also been used to help patients whose retina has come loose from the tissue behind it, a condition called retinal detachment. In this case, scar tissue caused by the burn holds the retina in place.

The surgeons intend to experiment with methods of artificially coloring clear parts of the eye to see whether such ailments as glaucoma or cataracts can be treated with the coagulator. These normally uncolored parts would then be burned by the light.

Glaucoma, the major cause of blindness in adults, affects a million people in the United States, including 2 out of every 100 persons over 40 years of age. It is caused by imperfect drainage of internal fluid of the eye, apparently resulting from a clogged drainage canal.

If some way can be found to color the meshwork leading to the canal, the coagulator might be able to burn an opening to allow drainage. Surgery is now required to correct cases of glaucoma which cannot be successfully treated by medicine.

At the present time experiments are already under way on animals to determine whether the glaucoma treatment method may prove feasible.

Customary treatment for cataracts is surgical removal of the patient's lens. The doctors expect to investigate the possibility of making the lens dark enough to absorb the light, so it might be obliterated without the usual surgery.

The light coagulator was invented by Prof. Gerd Meyer-Schwickerath of Bonn, Germany. He was a visiting lecturer at Stanford Medical School a year ago when the school was still located in San Francisco.

Prof. Meyer-Schwickerath first got the idea for the device after seeing patients with eclipse retinitis, or retina burns sustained while watching an eclipse of the sun without looking through smoked glass.

EYE DISEASE RESEARCH TOOL AT STANFORD MEDICAL CENTER

Stanford University surgeons are using a beam of light five times as intense as sunlight to explore new frontiers in the treatment of eye diseases, the Division of Ophthalmology announced today.

The beam comes from a $13,500 Zeiss light coagulator purchased with part of a $51,000 grant from the National Institutes of Health. The investigators are Dr. Milton Flocks, assistant clinical professor of surgery (ophthalmology), and Dr. H. Christian Zweng, clinical instructor in surgery (ophthalmology).

There are only a few of the light coagulators in use in the United States, the researchers report, and they are used almost entirely for treatment, particularly in cases of retinal detachment. Two of them are located in San Francisco at the University of California Medical Center and at Children's Hospital.

The Stanford grant is the only one made so far for research into new uses of the machine. It will finance three years of research.

The coagulator produces an intense beam which can be focused to a point. Light comes from a xenon tube and is so strong it is only left on for a fraction of a second when aimed at an eye. The beam is aimed with a shield in the way to reduce intensity. The shield is removed momentarily during treatment.

Because the light will pass through transparent tissue and liquid, the beam has been used to treat defects at the back of the eye. For example, the intense light will burn out a tumor on the retina, the light-sensitive coating that lines the rear of the eye.

--more--

The beam has also been used to help patients whose retina has come loose from the tissue behind it, a condition called retinal detachment. In this case, scar tissue caused by the burn holds the retina in place.

The surgeons intend to experiment with methods of artificially coloring clear parts of the eye to see whether such ailments as glaucoma or cataracts can be treated with the coagulator. These normally uncolored parts would then be burned by the light.

Glaucoma, the major cause of blindness in adults, affects a million people in the United States, including 2 out of every 100 persons over 40 years of age. It is caused by imperfect drainage of internal fluid of the eye, apparently resulting from a clogged drainage canal.

NOTE TO EDITORS: Your reporters and photographers are invited to a press conference for Dr. Linden at 1 p.m. on Monday, May 2, 1960. The press conference will be held in the Faculty Room, located in the Dean's Office, Room M 121, Stanford Medical Center, Palo Alto.

SEX PSYCHOLOGY LECTURES TO COVER "ROMANCE OF AGING"

Maurice E. Linden, M.D, Director of the Division of Mental Health of the Department of Public Health, Philadelphia, Pennsylvania, will give the 1960 Jake Gimbel Lectures on Sex Psychology on Monday through Wednesday, May 2-4.

The lectures, co-sponsored by Stanford University and the University of California, will be delivered Monday through Wednesday at 4:15 p.m. in Cubberley Auditorium in the School of Education Building, Stanford University Campus.

Two lectures covering the same subjects will also be given Tuesday and Wednesday evenings at 8 in the main auditorium of the Medical Sciences Building, University of California Medical Center, Parnassus Avenue near Arguello Avenue, San Francisco.

Dr. Linden's general topic will be "Romance of Aging." He will discuss the psychology of sex with respect to the process of aging in the United States.

Dr. Linden, a graduate of the Medical School of the University of California, has spent many years of study and research in the fields of psychiatry, psychoanalysis, mental health, and aging. He has served as Program Director of the Gerontologic Study Center in Norristown State Hospital, Norristown, Pennsylvania.

--more--

The title of the first lecture to be delivered at Stanford will be "The Modern Family--Breeding Ground of Character Problems." The sub-title will be "A Study in Sexual Role-reversal."

Using a historical perspective, Dr. Linden will look at the development of character and sexual maturity in the modern family. He will illustrate the lecture by comparing and contrasting an ancient Roman family and the American family following the first Industrial Revolution.

The Tuesday lecture at Stanford will deal with the "Fate of the Instincts." Dr. Linden will discuss the human life cycle as it relates to personality development. He will conclude with a comparison of infancy and senility.

"Climax and Antielimax" will be the title of Dr. Linden's final lecture at Stanford. This lecture will point out the sources of disappointment, frustration, and psychic trauma which may lead to personality breakdown with aging.

The topics of the two lectures to be given in San Francisco are: "Age Through the Ages--A History of Intergenerational Conflict," and "Growing Up or Growing Down--Aging and the Unconscious Mainstream."

The lectureship was established under the will of Jake Gimbel, a philanthropist who died in 1943. Previous speakers have included such famous people as Margaret Mead and Alfred C. Kinsey.

Dr. Linden is a member of the Committee on Aging of the Group for the Advancement of Psychiatry and the Committee on Aging of the American Psychiatric Association.

He is assistant professor in psychiatry at the University of Pennsylvania Medical School and a staff member of the Functional Clinic of the University of Pennsylvania Hospital. Dr. Linden is the author of numerous scientific and popular articles in his field.

LECTURE ON JOINT AND MUSCLE FUNCTION SCHEDULED

Dr. Jack Joseph, a faculty member of Guy's Hospital Medical School, London, England, will speak on "Practical Aspects of Joint and Muscle Function in Posture and Athletics" at the Stanford Medical Center on Wednesday, April 27.

The lecture will be held at 7:30 p.m. in Room 112 of the Medical School Building. It will be sponsored by the Stanford Department of Anatomy.

His speech will emphasize the nontechnical phases of research into body mechanics and will be of interest to persons in the fields of physical education and physical therapy as well as orthopedics.

Dr. Joseph participated in the International Anatomical Congress recently held in New York. He will fulfill speaking engagements at Stanford and the University of California Medical School. At the University of California he will speak to the Biomechanics Research Group and members of the Department of Orthopedics who arranged for his trip to the west coast.

Lectures are also scheduled at the medical schools of University of Chicago and Yale University.

FOR RELEASE: To P.M.'s, Wednesday, April 13, 1960 TELEPHONE DA 1-5310-11

NOTE TO EDITORS--The following is based on a scientific paper to be presented Wednesday morning, April 13, 1960, during the 44th annual meeting of the Federation of American Societies for Experimental Biology in Chicago. Release time is set to follow delivery of the paper.

STANFORD SCIENTISTS REPORT PROGRESS ON HEREDITY STUDIES

CHICAGO--Two Stanford University School of Medicine researchers reported today they are making progress toward determining the "code" of the very complex chemical which controls the heredity of animals, plants, bacteria and some viruses.

The chemical is deoxyribonucleic acid, known as DNA. Most scientists now believe that the sequence of just four materials within DNA makes the difference between individuals or between species. One DNA molecule is thousands of units long.

Dr. John Josse, who holds a postdoctoral fellowship from the National Foundation, delivered a paper on the research this morning at the 44th annual meeting of the Federation of American Societies for Experimental Biology. He is co-author of the paper with Dr. Arthur Kornberg, head of the Department of Biochemistry at Stanford. Dr. Kornberg shared the 1959 Nobel Prize in medicine.

While Drs. Josse and Kornberg could not study the sequence of the four materials in DNA, they did devise a method of studying pairs to find out the frequency with which one material follows another.

Explaining the work in lay terms, Josse compared the materials--adenine, guanine, thymine and cytosine--with cars in a train. It is as if the scientists were able to break the couplings between every other car to find out how often a box car follows a flat car, a tank car follows a gondola, etc.

--more--

The work shows that each DNA studied has a different frequency of pair sequences. In other words, the "code" chemicals aren't put together in a random way but each DNA has its own unique pattern.

There is no method now available for learning the complete sequence of a given DNA. While the new research by no means represents a complete sequence analysis of DNA, Dr. Josse said it is "a foot in the door" toward such understanding.

The researchers conducted detailed studies on 14 different types of DNA. Their samples were obtained from organisms ranging from tiny bacteria to a mammal (the calf).

Their technique involved making DNA in the laboratory and observing the way chemicals were incorporated into it. Complicated chemical methods, including tagging with a radioactive isotope and breaking down the product with a proper natural catalyst, were used to study the reaction.

Dr. Josse said the findings are consistent with previous assumptions about the way DNA is formed.

He stressed that there is still a great deal of research to be done before real understanding of the code these four materials represent is gained. "But this is a foot in the door in learning how these materials in the chain tend to follow one another."

Learning the hereditary code could have important significance in the future for understanding hereditary diseases.

STANFORD CLINICS RESUME SERVICES FOR HARD OF HEARING

PALO ALTO--The Stanford University Speech and Hearing Clinic next week will resume group instruction in lip reading for adults who are hard of hearing.

The program is run throughout the year except during academic vacation periods, according to Dr. Virgil A. Anderson, director of the clinic.

Lip reading classes are scheduled Mondays from 8:00 to 9:00 p.m., starting April 18.

The clinic is located in Edwards Building of the Stanford Medical Center, 300 Pasteur Drive, Palo Alto. Fees are nominal--$10 for the quarter.

All interested persons are invited to attend, Dr. Anderson said. The program allows for some individual therapy if needed.

The lip reading class is under the supervision of Miss M. Jo Eeckhout (cq); Miss Margaret Meeker is the therapist who teaches the class.

Further information may be obtained by calling the clinic at DAvenport 1-1200, extension 5416.

STANFORD STUDENT NURSES WILL DONATE A DAY OF HOSPITAL SERVICE

Young faces and new white uniforms will be seen in the medical and surgical corridors of the Palo Alto-Stanford Hospital on June 2. That day graduating student nurses will don the uniform of a registered nurse for the first time and donate a day of service to the hospital.

The student nurses have chosen to work an extra day without pay "to show their appreciation for the cooperation and support which the hospital nursing staff has given them," Miss Jane Knox, Instructor in Nursing, said. Students work on the hospital floors seven quarters during the course of their training at Stanford.

Early in the morning the students will meet for breakfast in the hospital dining room. They will report for duty at 9 a.m. in the surgical and medical areas and in the intensive care unit where they have been assigned.

The 1960 class will be the first to graduate under the new five-year curriculum and the first to express its appreciation to the nursing staff in this way. Sixteen of the 24 graduating students will participate in the event.

STANFORD MEDICAL SCHOOL NAMES DEPARTMENT OF MEDICINE EXECUTIVE

Dr. Halsted R. Holman, 35, today (MAY 19) was named Guggenhime Professor and Executive of the Department of Medicine at Stanford University School of Medicine.

His appointment was approved by the University trustees at their meeting in San Francisco. It is effective July 1.

Holman is now on the staff of the Rockefeller Institute for Medical Research in New York City.

"Dr. Holman typifies the modern physician, well grounded in natural science and clinical medicine," Dean Robert H. Alway of the School of Medicine said. "He clearly understands the art of medicine--concern for patient care and competence in the application of medical science to everyday problems--as well as the need for excellence in the basic sciences."

Holman succeeds Dr. David A. Rytand, Bloomfield Professor of Medicine, as head of the department. Dr. Rytand has been departmental executive since 1954 but asked to be relieved of his administrative duties two years ago. He remains on the faculty as Bloomfield Professor.

The Stanford appointee is the first Guggenhime Professor. The Berthold and Belle N. Guggenhime Professorship was established with a bequest from the estate of the late Mrs. Guggenhime. The Guggenhimes' nephew, Richard E. Guggenhime of San Francisco, is a member of the Stanford University Board of Trustees.

(more)

Dr. Holman has a Stanford background. His parents are Dr. Emile F. Holman, Emeritus Professor of Surgery, and Dr. Ann Purdy (Mrs. Holman), Emeritus Clinical Professor of Pediatrics, who live in San Francisco.

Dr. Emile Holman was on the Stanford faculty for 30 years before his retirement in 1955. He was Executive of the Department of Surgery from 1926 to 1942 and from 1945 to 1955.

Following study at Stanford and U.C.L.A., Dr. Holman entered Yale University School of Medicine. He received his M.D. from that university in 1949.

In 1949-50 he was a National Research Council Fellow in Biochemistry at Carlsberg, Copenhagen, with Dr. Kaj Linderstrom-Lang. He received his clinical training at the Montefiore Hospital in New York City. He has been at the Rockefeller Institute since 1955.

Dr. Holman's major fields of interest are immunology and the rheumatic diseases. He is a member of Alpha Omega Alpha, the American Society for Clinical Investigation, Sigma Xi, the Harvey Society and the American Rheumatism Society.

Dr. Holman is married and has three children. His wife, Barbara, is a graduate in nursing from Yale and has a Ph.D. in public health from that university.

AUSTRALIAN BIOLOGIST TO DELIVER HERZSTEIN LECTURES

Eminent Australian biologist Sir Macfarlane Burnet, M.D., Ph.D., F.R.S., will speak on the "Problems of Immunity" at the seventeenth course of Herzstein Medical Lectures, sponsored by the medical schools of Stanford University and University of California.

The lectures will be held on May 24, 26-27 at 8:15 p.m. in the auditorium of the San Francisco County Medical Society, 250 Masonic Avenue, San Francisco.

Sir Macfarlane is Director of the Walter and Eliza Hall Institute of Medical Research in Melbourne and Professor of Experimental Medicine at the University of Melbourne. He has recently written three textbooks on immunity, which were published by the Cambridge University Press.

His research has dealt with the general field of infectious disease, but since 1940 has been concentrated on influenza and the influenza viruses. In 1958 he received the Order of Merit from Queen Elizabeth and this year the Copley Medal from the Royal Society for his contributions to virus research and immunology.

Lectures scheduled are: Tuesday, May 24, "Clonal Selection Theory After Three Years;" Thursday, May 26, "The Simonsen Phenomenon as a Laboratory Model of Autoimmune Disease," and Friday, May 27, "Autoimmune Disease in Man--Some Theoretical Considerations."

The lectures will be open to the public. Members of the medical profession, medical students, and other interested persons are invited to attend.

NURSES HOLD WORKSHOP ON PERSONNEL GUIDANCE

Stanford professor Arthur P. Coladarci and management expert Bert Smith will be featured speakers at the first workshop for head nurses and supervisors at Palo Alto-Stanford Hospital Center this week.

The purpose of the workshop is to provide better patient care by training professional nurses in the guidance of nursing aides, orderlies, nursing clerks, and Licensed Vocational Nurses--personnel who assist with much of the patient care in the hospital. Sessions will be held on both Thursday and Friday.

According to Miss Marjorie Keys, Director of Nursing Service Education and Training, the workshop is also aimed at educating professional nurses so they will "get satisfaction from personnel guidance as well as bedside nursing."

With the new concept of team nursing and the recent shortage of registered nurses, the bedside nurse of yesterday is rapidly becoming a professional leader in nursing today, she said.

The workshop will be given by the Department of Nursing Service. Mrs. Darlene Lutts, Director of Nursing Service, will open and close the conference.

Dr. Coladarci, Professor of Education and Psychology, will speak to the nurses Thursday afternoon. He will discuss the importance of a clear system of communication between professional nurses and the auxiliary personnel.

--more--

Smith, of C.H.&D. Sugar Refining Company and a visiting lecturer at Contra Costa College, will address the group Friday morning on "The Appraisal Process: Methods and Tools Utilized By Management". Also speaking to the nurses will be Dr. E. Dwight Barnett, M.D., Administrator of the Hospital Center. His topic will be "Role of the Nurse as a Professional Person".

A panel of physicians will conclude the workshop on Friday afternoon. Taking part in the final session on "What We Expect of the Professional Nurse" will be Dr. Barnett, Dr. A. S. Felsovanyi, Palo Alto Medical Staff; Dr. E. W. Fredell, Chief of Palo Alto Medical Staff, and Dr. Andrew Hunt, Director of the Stanford Clinics. Moderator will be Miss Virginia Brown, Associate Administrator.

Professional nurses who will participate in the sessions are: Mrs. Clare Mynderse, Miss Lois Williams, Miss Barbara Webber, Mrs. Esther Grow, Miss Jane Knox, Miss Doris Moberg, Mrs. Mary Michel, and Mrs. Patricia Fogelstrom.

Taking part in a panel discussion on "The Appraisal Process Used By Head Nurses" will be Miss Jean Butler, Mrs. Doris Fau, Miss Virginia Booth, and Miss Rachel Kopp.

"ON LOCATION" CAREERS CONFERENCE SLATED

Palo Alto- Stanford Hospital Center will sponsor a Medical Careers Conference on Wednesday, May 11, at which local teenagers will have a chance to see medical specialists at work "on location".

The conference will be the major event given by the Center in conjunction with Hospital Week, May 8-14. Open to all local high school students, its purpose will be to interest young people in medical careers. It will be held from 3:30 p.m. to 5:30 in the Center.

The hospital lobby will be the starting place for a series of six tours to six different hospital departments. Staff of the six departments will demonstrate their jobs for the teenagers in their laboratories and offices.

Taking part in the demonstrations will be a laboratory technician, dietitians, a physician, speech and hearing specialists, physical and occupational therapists, and nurses.

Chief technician in the clinical laboratory, Miss Ellen Charlton, will show the groups the setup for blood typing and cross matching patients receiving transfusions. She will also compare normal and abnormal blood smears.

Dietitians, Helen Anderson, Joan Nevins, and Esther Sippel, will show various types of meals prepared for patients. Also scheduled is a tour of the kitchen with its 80 gallon kettles and walk-in refrigerator which are necessary for the preparation of 2,400 meals a day.

--more--

Students will get a chance to participate in hearing evaluation tests in the Speech and Hearing Clinic. Physical therapist Catharine Graham and occupational therapist Elizabeth Harper will demonstrate equipment used in the treatment of handicapped patients.

Nurses, Miss Marjorie Keys, Mrs. Esther Grow, and Mrs. Darlene Lutts, will use a model as patient to show how the new concept of team nursing operates in the Hospital Center. Results from a physical examination will be shown and explained by a physician.

UPON RECEIPT

Seven employees of the Palo Alto-Stanford Hospital Center have received awards for fifteen years of hospital employment, and one employee has received an award for thirty years' service.

Gail S. Reeves was awarded a gold pin for thirty years of work in the Stanford Hospital in San Francisco and the Hospital Center. She was honored for her work as a bacteriologist in the Infectious Diseases Department.

Of the seven women receiving silver pins for fifteen years of service, three have served in the Palo Alto Hospital and then the Hospital Center. They are Marguerite K. Brickner, R.N.; Johanna Motmans, R.N., and Irene T. Springer, Nursing Service.

Also receiving silver pins for fifteen years were Helen H. Anderson, Ruth E. Cline, and Esther L. Sippel, all of the Dietary Department, and Imogene J. Robertson, Infectious Diseases Department. These women were employed by the Stanford Hospital in San Francisco and received credit for their experience on transferring to the Hospital Center.

The annual Gold and Silver Award Banquet was held recently in the Center. Speakers were Dr. E. W. Fredell, Chief of Staff; William R. Hewlett, President of the Board of Hospital Directors, and Helen Anderson, Director of Dietetics.

STANFORD PROFESSOR AND STUDENTS TO STUDY TROPICAL DISEASES IN CENTRAL AMERICA

Dr. Quentin M. Geiman, professor of preventive medicine, and two students from the Stanford University School of Medicine will leave June 30 to study problems in tropical health for two months in Central America.

The students are Ali Abdul-Ilah Seif of Yemen and Kuo-Ping Yu of the Philippines. They will finish medical school next year. Both young men plan to return to their native countries to work after graduation.

Dr. Geiman and the students will assist in caring for patients at hospitals in Panama, Costa Rica and El Salvador. They will also conduct field studies of certain tropical diseases.

Their trip is financed by a training grant in tropical health from the U.S. Public Health Service. This training program has been in progress since October, 1959. Since January it has been conducted with the help of Dr. Charles B. Beal, another staff member of the Department of Preventive Medicine.

EDUCATIONAL FUND TO BE ESTABLISHED IN HONOR OF DR. E. DWIGHT BARNETT

The administrative staff of the Palo Alto-Stanford Hospital Center has donated $500 as the first step toward establishing the E. Dwight Barnett Educational Endowment Fund at the Hospital, it was announced today.

The proposed purpose of the fund will be to help defray Hospital expenses in connection with medical-related education and training for employees. It is hoped this will stimulate public interest and participation in supporting such undertakings.

The fund will honor Dr. E. Dwight Barnett, who resigned last week as administrator of the Hospital.

In advising Dr. Barnett of the plans for the fund, William R. Hewlett, president of the Hospital Center's board of directors, said it was being established "in gratitude for your tireless devotion as administrator...; to acknowledge your outstanding contributions in medical and paramedical education; and as a tribute to the visions you hold of a university-community medical center devoted to the highest standards of patient care and medical education."

Initially, income from the fund may be used for achievement awards, employee training and similar purposes. As sufficient funds become available, income could be used to cover some of the Hospital's expenses in maintaining intern and resident programs, not only in medicine but in other fields such as dietary service, hospital administration and the like.

Officials said that once the fund is legally created they hope the trustees of the fund will solicit contributions so that there will eventually be an endowment of more than a million dollars.

Dr. Barnett is a nationally-recognized authority in administrative medicine. Before he became administrator of the Hospital Center in 1958 he was professor of administrative medicine at Columbia University's School of Public Health and Administrative Medicine in New York City. He also is a member of many advisory and professional organizations in the field.

STANFORD SCHOOL OF MEDICINE HONORS TOP STUDENTS

Fifteen students in the Stanford University School of Medicine, Stanford, California, were honored for their outstanding work during this year.

Six students in the class of 1960 received awards at the annual Senior-Faculty Dinner in June. Richard R. Babb of Wilmington, Ohio, won the Hopkins Award of $100 for outstanding work in dermatology and was one of five students to win the Mosby Scholarship Book Award of $30.

Also awarded the Mosby prize were 1960 graduates, Cooley Butler, II, of Los Angeles; Charles Comfort of San Mateo, Calif., Melvin D. Flamm, Jr., of San Francisco, and Gregor M. Wilkinson of Pacific Palisades, Calif.

Joseph Van De Water of Ray, Ariz., received the Robert T. Legge Award of a book for the student showing the greatest interest and accomplishment in the field of occupational health.

Palo Alto-Stanford Hospital intern Gary R. Katz, M.D., of Hollywood won the Julian Wolfsohn Award of $100 for his work in internal medicine and neurology, and Victor R. Lavis of Los Angeles received the Roche Award as the outstanding student in the second year class.

Several students were named to Alpha Omega Alpha, national honorary medical fraternity, this year. Members from the class of 1960 are Walter F. Alexander, Sacramento, Calif.; Roger V. Cadol, Menlo Park, Calif.; Keith E. Cohn, San Francisco; Lowell M. Hill, Rolling Hills, Calif.; John M. Palmer, Berkeley, Calif.; Babb, Butler, Flamm, and Wilkinson.

--more--

Elected to AOA this spring were Donald M. Mason, Mankato, Minn., and John M. Simpson, Jr., Salt Lake City, Utah, members of the class of 1961.

EDITORS: Parents' names and addresses follow:

Walter F. Alexander, Jr., Mr. and Mrs. Walter F. Alexander, 912-46th St., SACRAMENTO, CALIF.

MOTHER OF FIVE TO RECEIVE M.D. DEGREE

Proving that a woman can be a professional in the fields of both medicine and maternity, Joan Altekruse will receive her M.D. degree from Stanford on Sunday (JUNE 12), just three months before her sixth child is due to be born.

Mrs. Altekruse has gone through medical school in four straight years although one of her five children was born in 1956, two weeks before she began, and one in 1958 during medical school.

Nor is she the only medical student in the family. Her husband, Ernest, will begin his second year at Stanford University School of Medicine this fall.

Now that Joan has earned her degree, she won't rest on her laurels, however. She plans to intern at the U.S. Public Health Service Hospital in San Francisco for a year beginning July 1. She interned two weeks during the spring so she can take time off when the baby arrives in September.

While Joan has been studying, her husband has followed a rigorous military and academic schedule himself. He resigned his commission as a major in the Marine Corps last year after 10 years in the service. In the Marines he took night school courses in pre-medical subjects. During the next three years Ernie hopes to take advantage of the free time in the medical curriculum at Stanford to study electronics as well as medical subjects.

--more--

Good teamwork and an early bedtime for the children enabled Joan to tackle her two jobs with equal success. Sundown study sessions were held at the dining room table after the dishes were cleared off and the children were in bed. In addition, they have had regular household help.

The financial burden of tuition and books for both parents was eased by a Hewlett-Packard fellowship Ernie won last year and which was renewed for next year. In previous years the family found it possible "to live on and save from the Marine salary."

The Altekruses both entered Stanford last fall. Joan transferred from George Washington University Medical School, where she studied for three years when her husband was stationed overseas and in Washington, D.C.

"Ernie wanted to study at Stanford because of the five-year curriculum which allows medical students to take outside courses," Joan said. His interest in medicine grew out of work in medical electronics with the Marine Corps.

In 1956 he received an M.A. in electronics from the U.S. Naval Post-graduate School in Monterey. He was graduated from the U.S. Coast Guard Academy in 1949.

During the year the family lived in Monterey, Joan took graduate work at Stanford's Hopkins Marine Station in Pacific Grove. She met Ernie in 1949, the year she was graduated from Vassar College, when they were both second lieutenants in the Marine Corps. They were married in 1950.

The student-parents foresee an easier schedule next year with five of their soon-to-be-six children in school. Philip, 6; Clifford, 5, and Lisa, 4, will attend the new Escondido Village Elementary School in the fall, while Jan, 3, and Ernest, Jr., 1, will be in Escondido Village Nursery School. All the children have birthdays this summer.

The Altekruses live at 5D Escondido Village, Stanford.

EYE BANK NOW OPEN AT STANFORD MEDICAL CENTER

The Stanford Eye Bank is now in operation at Stanford Medical Center, Dr. Frank C. Winter, acting head of the Division of Ophthalmology, announced today. The bank was previously located in San Francisco when the Stanford University School of Medicine was there.

The bank does not store eyes except for the short period before they are used in operations. It is really a file of more than 1,200 names and addresses of people who have offered to donate their eyes when they die.

The bank does not charge patients or doctors for its services, nor are eyes bought or sold, Dr. Winter said. Contributions support the bank.

Eyes must be removed within six hours of a donor's death. They must be used for a corneal transplant within 48 hours of death. The cornea is the transparent front covering of the eyeball. Transplants are frequently used to help patients with cloudy, scarred or distorted corneas.

When a donor dies his eyes are removed and brought to the bank or to any other hospital where the operation may be performed. A patient needing a transplant is notified and goes to the hospital for surgery.

In the past the bank has supplied corneas for patients throughout the Bay Area and Northern California as far south as Salinas and Monterey.

The bank's files were divided between San Francisco-Stanford Hospital and Palo Alto-Stanford Hospital when the medical school moved last fall, the latter taking all names south of Daly City. The Presbyterian Medical Center in San Francisco is now operating the bank in that city.

Prospective donors may get additional information by writing the Stanford Eye Bank, Stanford Medical Center, 300 Pasteur Dr., Palo Alto, or by calling DAvenport 1-1200, extension 5517.

SIX NEW FACULTY MEMBERS NAMED BY MEDICAL SCHOOL

The chief of anesthesia and the director of the Rehabilitation Services are among six new appointments to the faculty of Stanford University School of Medicine. The appointments will be effective for the next academic year.

Dr. John P. Bunker will be professor and chief of anesthesia. He is now on the staff of the Massachusetts General Hospital and assistant clinical professor of anesthesia at Harvard Medical School.

Dr. Bunker was certified by the American Board of Anesthesiology in 1953. A Harvard graduate, he received his A.B. degree in 1942 and his M.D. degree in 1945 from Harvard.

Dr. Daniel J. Feldman was appointed director of the Rehabilitation Services and associate professor of medicine. He is now associate professor at New York University School of Medicine in the Institute of Physical Medicine and Rehabilitation.

Dr. Feldman was trained in internal medicine and physical medicine and is board accredited in both specialties. A graduate of Columbia University in liberal arts, he earned an M.D. degree in 1938 from New York University School of Medicine.

Dr. Feldman will replace Dr. Rodney R. Beard as director of the Rehabilitation Services. Dr. Beard, who has directed the services since 1955, will continue as professor and executive of the Department of Preventive Medicine.

--more--

Other new appointments include:

Dr. J. Weldon Bellville will be associate professor of anesthesia. Dr. Bellville has been assistant professor at Cornell University Medical College since 1959. A research fellow for Sloan-Kettering Institute in 1955-56, he returned to be an assistant in its division of experimental surgery in 1958.

Dr. Herbert C. Schwartz was appointed an assistant professor of pediatrics. He has been research instructor in medicine (hematology) at the University of Utah since 1958. He is a graduate of Yale University and New York State University College of Medicine in Brooklyn, where in 1952 he won his M.D. degree.

Also named assistant professors were Dr. R. Bruce Jessup and Dr. Gustav J. Nossal in pediatrics and genetics respectively. Dr. Jessup has been acting assistant professor at Stanford and Dr. Nossal a research associate.

STANFORD SKIN SPECIALIST NAMED VISITING PROFESSOR IN VENEZUELA

Dr. Eugene M. Farber, professor and head of the dermatology division of Stanford University School of Medicine, is in Caracas, Venezuela, to serve as visiting professor at Central University of Venezuela.

During his three-week stay in Caracas Dr. Farber will help set up modern graduate training and research programs in dermatology. That is the medical specialty concerned with skin diseases.

Dr. Farber will give three lectures to medical groups in Caracas and will also make field trips to villages and to care centers for leprosy patients. He arrived in Caracas July 18.

The Stanford professor is an internationally recognized authority on skin ailments. At present he is directing an extensive multi-discipli attack on psoriasis, the disfiguring skin disease which afflicts between 3 and 4 million Americans.

Mrs. Farber and two of their four children accompanied Dr. Farber to Venezuela. The Farbers live at 167 Ramoso Rd., Portola Valley.

NEW HOUSE STAFF ARRIVE AT PALO ALTO-STANFORD HOSPITAL CENTER

Seventy-two new house officers and four new dietary interns are now on duty at Palo Alto-Stanford Hospital Center, according to David Starkweather, associate administrator for professional and outpatient services.

The house officer category includes all the doctors who are interns, residents, trainees and fellows. They assist in the care of all teaching patients in the Hospital and in the Stanford Clinics. Some are also assigned to the emergency, operating and delivery rooms, where they serve both teaching and private patients.

All told the house staff for the year ending next July totals 145, although some of the doctors will work part of the time at other hospitals associated with Stanford. These other hospitals include the Menlo Park and Palo Alto Veterans Administration Hospitals, San Mateo Community Hospital, Santa Clara County Hospital in San Jose, The Stanford Convalescent Home and Presbyterian Hospital and Medical Center in San Francisco.

All of the young doctors care for patients but some are called trainees or fellows because they have received training grants or fellowships. The Hospital pays the salary of interns and residents who work there.

The dietary interns are young women who have completed their undergraduate training. They will work in the dietary department of the Hospital for a year getting practical experience planning, preparing and serving regular and special therapeutic meals. Seven more are scheduled to arrive in September.

WORKSHOP ON HEARING PROBLEMS TO BE HELD AT STANFORD

The physiology of hearing problems and rehabilitation of the hard of hearing is the topic of a workshop to be held at Stanford University this month. It will be co-sponsored by the Division of Speech Pathology and Audiology and the Hearing Aid Industry Conference, an organization of leading manufacturers of hearing aids.

About 75 hearing aid dealers from the western states, Hawaii and Canada are expected to attend sessions, which will open Sunday, July 17, on the Stanford campus and will run for four days through July 20. Some of the speakers at the workshop will participate in the TV program, Doctors News Conference, KTVU, Channel 2, on Tuesday evening, July 19, at 8.

The workshop is one of three co-sponsored this year by universities and the HAIC. Its aim is to train hearing aid dealers to do a better job of assisting the estimated 5,000,000 Americans with problems that can be corrected with hearing aids. Experts in the field of audiology lectured for the group last June under the auspices of Northwestern University and the HAIC. Another workshop is slated for September at the University of Pittsburgh.

Participants in the Stanford workshop will include: workshop chairman, Hayes A. Newby, Ph.D., Professor of Speech Pathology and Audiology, Stanford School of Medicine; Vincent Salmon, Ph.D., Manager, Sonics Section, Stanford Research Institute; Victor Goodhill, M.D., Clinical Professor of Surgery, (Otology), University of Southern California School of Medicine; S. Richard Silverman, Ph.D., Director, Central Institute for the Deaf, and Professor

--more--

of Audiology, Washington University, St. Louis, Mo..

Other speakers will be Leo G. Doerfler, Ph.D., Professor and Director, Department of Audiology, University of Pittsburgh School of Medicine; Kenneth O. Johnson, Ph.D., Executive Secretary, American Speech and Hearing Association, Washington, D.C., and Raymond T. Carhart, Ph.D., Professor of Audiology, Northwestern University.

Dr. Goodhill, Dr. Doerfler, and Dr. Silverman will be panelists on Doctors News Conference, with Dr. Newby acting as moderator.

NOTE TO EDITORS: The following news story is based on a scientific paper which will be delivered at the meeting of the American Association of Blood Banks in San Francisco. The release time is set to follow delivery of the paper.

FOR RELEASE to P.M. newspapers of Thursday, August 25, 1960.

Population studies based on findings by a Stanford University School of Medicine investigator have provided scientists with a new tool for research into human heredity.

The results, according to Research Associate Rose Payne of Stanford, show that white blood cell factors in humans are genetically determined.

There are now available only a limited number of normal genetic "markers" suitable for studying human heredity. These include the red cell blood groups, (ABO, Rh, etc.) which have been extensively used. Many studies in the past have depended upon abnormal human conditions.

The results were reported today by Dr. Payne and Dr. Emanuel Hackel, Associate Professor of Natural Science at Michigan State University. Dr. Hackel read their joint paper at the annual meeting of the American Association of Blood Banks in San Francisco.

The study was based on analysis of white blood cell factors in 53 families, they said. Samples from the families were tested with up to 20 types of blood serum which are known to have antibodies to the cells, called leukocytes.

This type of antibody was discovered eight years ago among patients who had received a large number of blood transfusions. These antibodies are produced as a result of exposure to leukocytes of different types than the type an individual is born with.

--more--

Since that time Dr. Payne has found many more examples of such antibody production during pregnancy. If a mother and father have white cells of different types and the child inherits the father's type, the baby may stimulate antibody formation in the same way an Rh-positive baby will stimulate them in an Rh-negative mother.

Subsequent transfusions to individuals having leukocyte antibodies may induce a reaction of chills and fever. This reaction is similar to that encountered in cases of red cell incompatibility, though much less severe.

Dr. Payne's tests identified the presence of various leukocyte factors in family members. Dr. Hackel, a geneticist, then studied the incidence of the types among the families to establish their hereditary nature.

"The population studies show there is a definite pattern of inheritance," the investigators reported. They said it is too early to know the exact number of leukocyte types in humans.

Eventually they anticipate that people may be typed for white blood cells as they now are for red cells so that the reaction to transfusion can be avoided. Sensitized patients today are given transfusions which have the leukocytes removed.

Drs. Payne and Hackel believe, however, the most important effect of the present report will be to give scientists additional means for studying how characters are passed from one generation to the next.

This research is supported by grants from the National Institutes of Health and the American Cancer Society.

Samuel Moffat, DA 1-5310

NOTE TO EDITORS: The following news story is based on a scientific paper which will be delivered at the meeting of the American Physiological Society at Stanford. The release time is set to follow delivery of the paper.

FOR RELEASE to A.M. newspapers of Thursday, August 25, 1960

Two investigators at the Stanford University School of Medicine have found the explanation for the severe diarrhea which is the major cause of death in cholera patients.

The husband-and-wife team of Geraldine and Frederick Fuhrman reported at the American Physiological Society meeting at Stanford yesterday that the toxin given off by the cholera organism inhibits the absorption of salt by the intestine.

This largely prevents the absortion of water, since the water is taken up only together with salt. Accordingly, water accumulates in the intestines and diarrhea occurs.

Until now, Dr. and Mrs. Fuhrman said, nobody knew why cholera patients get diarrhea. The tremendous loss of fluid from the body results in dehydration which frequently leads to death.

Cholera has not been reported in the western hemisphere since the 19th century, but it is still a major health problem in Asia. An epidemic was reported in West Pakistan earlier this month.

The disease claims tens of thousands annually in Asia and is a menace to other parts of the world. In 1947 Egypt experienced a cholera epidemic, although the disease had disappeared there after 1919.

--more--

FILE COPY

Mrs. Fuhrman is a research associate in the Basic Medical Sciences Laboratories. Her husband is professor and director of the laboratories.

Professor Fuhrman said that he does not foresee any application of the findings in prevention of the disease. However, he pointed out that knowledge of the happenings in the course of a disease is valuable in finding ways of preventing them.

There is at present no satisfactory specific treatment for cholera, although salt solution is fed into patient's veins to replace water and salt. This treatment does reduce the death rate.

The Fuhrmans made their discovery by measuring the flow of charged particles of sodium from salt solution through a piece of frog skin and through the frog's stomach. The sodium was a radioactive isotope so its presence could be detected after it had passed through the tissue.

When the cholera toxin, the poison given off by the micro-organism which causes the disease, was put into the solution, the passage of sodium was cut to almost zero.

Frog skin was used because this tissue moves salts and water in a manner very similar to intestine, but is a simpler tissue.

Mrs. Fuhrman said the findings are clearly applicable to the action of the cholera toxin in human intestines, as well as to the action of many other toxins causing diarrhea.

The investigators are now studying the cholera toxin to determine what part of it is the active agent in the process.

MAJOR SCIENCE MEETING SET AT STANFORD MEDICAL CENTER

Stanford University and the University of California are joint hosts for more than 700 scientists who are expected to attend the 12th annual meeting of the American Physiological Society at Stanford Medical Center August 23, 24 and 26.

Sessions will be held at the University of California Medical Center in San Francisco on August 25, according to Stanford Professor Jefferson M. Crismon, co-chairman of the steering committee.

A total of 360 papers will be given by investigators from 36 states and 7 foreign countries. The Society is the major professional organization of physiologists in this country.

Physiology is the science that deals with the functions of living organisms. It is concerned with what the parts of animals and plants do and how they do it, as contrasted with anatomy, the study of the structure of organisms.

The meeting is essentially concerned with basic investigations which are aimed at finding new facts, whether or not these have possible practical applications.

However, some of the findings to be reported shed light on human ailments and problems. Reports of this sort deal with new information about the operation of the heart, the effects of smoking, the effects of acceleration as in space travel, and other subjects.

The research papers will be presented at Stanford August 24 and 26. On August 23 there will be a refresher course. Sessions will be held at the Medical Center, in the Physics Lecture Hall, the Anatomy Lecture Room and Schultz Auditorium.

At the UC Medical Center Dr. Carl W. Gottschalk of the University of North Carolina will deliver the fifth annual Bowditch lecture on "Micropuncture Studies of Tubular Function in the Mammalian Kidney." Scientific symposia will also be held there the morning of August 25.

MEMO TO SCIENCE WRITERS, CITY EDITORS AND NEWS EDITORS

Mrs. Judith G. Pool of 3334 Clay Street, San Francisco (Home phone JO 7-0586), a research associate in medicine at the Stanford University School of Medicine, has prepared a display for the meeting of the American Association of Blood Banks in San Francisco August 21-26.

The display deals with the preservation of two anticoagulant factors in stored blood which are essential if the blood is used for patients who are bleeding or have coagulation problems.

The display is entitled "Preservation of Antihemophilic Globulin (AHG) and Proaccelerin in Stored Blood." It is based on research by Dr. Pool and by Dr. Samuel Rapaport of the University of Southern California School of Medicine. The display will be set up at the Jack Tar Hotel this weekend.

Dr. Pool said her recommendations for processing blood to preserve the two factors are important for all blood banks, since any bank may have to supply blood for a patient with hemophilia, the so called "bleeder's disease."

Her four basic recommendations are as follows: There should be (1) efficient mixing with anticoagulant when the blood is first collected; (2) quick separation of plasma from whole blood; (3) processing at low temperatures at all times; and (4) quick freezing after separation.

She also said that it is not advisable to store the blood for more than three months, which is about the usual length of storage.

"ON-THE-JOB EVALUATION SET UP FOR REHABILITATION PATIENTS

Several weeks ago a 45-year-old woman went to work in the Palo Alto-Stanford Hospital Center gift shop, which is customarily staffed by members of the Hospital Center Auxiliary.

But, this woman was not a member of the Auxiliary. She was a cerebral palsy patient who, because of her handicap, had never worked before in her life. The motions of waiting on customers were difficult for her and she was afraid that customers would leave the counter because she could not serve them swiftly enough.

Today the patient, sponsored by the State Vocational Rehabilitation Service, is getting further training in the Goodwill Industries' store in San Jose. She was able to tackle the job of clerking in the Hospital Center and the state service decided that the woman was not incapable of working as had been supposed earlier.

This woman is one of eight patients who have taken four-day "jobs" in the Stanford Medical Center since spring under a new program of the Vocational Services Division of the School of Medicine's Rehabilitation Services. The program gives handicapped persons a chance to test their abilities in actual working situations as a preliminary test before they face the pressures of working in a salaried job.

The program is aimed at further evaluating a rehabilitation patient's ability to adapt to a job. As in the case of the woman above it may give patients the confidence to try to find work which they can handle. It may also save some patients from undertaking jobs when they are physically or emotionally unable to handle the work.

--more--

Directed by Martin Acker, chief of vocational services, it is being developed with the cooperation of many departments of the Hospital Center, the Medical School, and Stanford University itself. It is an example of the cooperative effort which is a part of the Stanford Medical Center.

Palo Alto-Stanford Hospital is one of only three private hospitals in the country which have such a program, as far as is known here. Others are Massachusetts General Hospital in Boston and Cedars of Lebanon Hospital in Los Angeles. Public hospitals, including those of the Veterans Administration, have had this service in the past.

This is the third step in the Medical School's vocational program for the disabled. Until last year only aptitude and achievement tests could be offered. In October a second step became available in the prevocational laboratory, supported largely by the National Foundation. There patients test their manual skills in such operations as sorting, packaging, and office machine work.

Many of the laboratory tests provide opportunities for the patient to do real work for other Center departments rather than simulated exercises.

However, many patients who have never worked before or have been unemployed for a long time are afraid that they will not be able to adjust to working with people and to taking orders. The work program gives patients a chance to adjust to this phase of employment.

Only evaluation is provided. The patient does not get a salary and is not offered a job in the Hospital. He works up to four days in a department but does not do any work concerned with patient care.

Housekeeping, Stores, Central Supply, Volunteer and Messenger Services, the Animal Facilities and Dietetics have taken part in the program. The departments have benefitted from the "bonus" work, Acker says. In addition, personnel not usually associated with care of

patients "have had a chance to contribute to therapy and rehabilitation."

Expansion of "this pioneering adventure" to campus departments is already planned, the counselor said. Utilizing the campus and Center areas, a patient will be able to try his hand in practically any manual job a community can provide, Acker said.

The program will eventually serve all patients disabled by injuries and crippling disease who seek jobs. "By fall," Acker said, "we plan to have a patient on a job site every day."

MEMO TO CITY DESKS, NEWS DESKS, AND SCIENCE REPORTERS

On August 24 and 26, 1960, scientific papers will be given at Stanford during the 12th Annual Meeting of the American Physiological Society. A press room will be set up in Stanford Medical Center and your reporters are invited to attend.

The following stories are ones which appear to be most interesting from a layman's point of view. Abstracts of them will be available in the press room. In addition, the speakers have been asked to submit one-page summaries in lay language. Press conferences will be arranged at the request of reporters.

Would you please let us know whether a reporter will be attending from your organization. This will help us in planning to be sure enough space is available.

POTENTIAL STORIES

(Numbers refer to the listings in the program of the meeting.)

SMOKING: Effects of nicotine on growth of animal cells (with comments on cigarette filters) (80)
Effect of smoking on lung performance (310)
Cigarette smoking and fatigue (320)

SPACE MEDICINE: Effect of acceleration on heart output (10)
Effect of gravity on growth of mice (84)

HYPNOSIS: Effects of hynosis on kidney function (231)

BREATHING: Regulation of breathing in dogs (31)
Effect of breath holding on the possibility of drowning (36)

HEART AND CIRCULATION: New information about the heart (13,17,21)
Possible new tool for treating shock and heart failure (107)
A simple method of repairing blood vessels in disaster (110)
Effect of heart stoppage on brains of dogs (124)
Oxygen supply to mother and young in pregnancy and delivery in cats, rabbits and guinea pigs (125)

OTHER DISEASES: Explanation for the cause of diarrhea in cholera (132)
Blood flow in skin of patients with psoriasis (68)
Biochemical findings related to two mental diseases (335,336)
Study of anticoagulant factor in blood of hemophilia patients (163)
Study in dogs suggests adrenal corticoids could increase occurrence of stomach ulcers (227)

MISCELLANEOUS: Sex differences in brain excitability of rats (61)
Water and salt storage in pregnant rats (48)
Spawning salmon, patient with Cushing's syndrome have common characteristics (96)

$395,028 GRANT TO SUPPORT DISEASE STUDY AT STANFORD MEDICAL CENTER

The John A. Hartford Foundation, Inc., of New York City has made a $395,028 grant for a three-year study at Stanford Medical Center of diseases of hereditary and developmental origin, it was announced today.

The research will begin September 1 under the direction of the Pediatrics Department of the Stanford University School of Medicine. The grant was announced today by Mr. Ralph W. Burger, President of the Foundation.

The grant will support a multi-discipline investigation aimed at understanding and finding methods of treatment for these diseases, which have recently assumed dramatic proportions in modern American medicine.

Disorders such as cystic fibrosis, diabetes mellitus, hemolytic anemias and various types of dwarfism will be studied in human patients as well as in laboratory animals. The basic approach will be to investigate the chemistry of life processes in animals before birth.

In addition, a case-finding center for northern California will be established at Stanford which will eventually offer opportunities for care of patients as well as counseling for them and their families.

Several million Americans of all ages are afflicted with genetic or developmental diseases and the total is increasing annually. The ailments are particularly numerous among children since recent advances in medical care have reduced the serious consequences of infectious diseases like pneumonia, meningitis, and so on.

--more--

Dr. Norman Kretchmer, professor of pediatrics and executive of the department at Stanford, will be the principal investigator. He will be assisted by several other faculty members, including Dr. Kenneth Tsuboi, Dr. Sumner Yaffe, Dr. Herbert Schwartz and Dr. Robert Greenberg. Another participant will be Dr. Robert Jacquot of the Department of Comparative Physiology, University of Paris, France, who will be a visiting assistant professor at Stanford.

The Hartford Foundation was originally established by John A. Hartford, former president of the Great Atlantic & Pacific Tea Company, who left it the bulk of his estate. His brother, George L. Hartford, former chairman of the board, left his entire estate to the Foundation.

The research project underscores the particular interest of the Pediatrics Department in problems of growth and development, Dr. Kretchmer said.

It is proposed that approximately $38,000 of the grant will be used for preparing laboratory facilities at the Stanford Convalescent Home near the medical school.

The research program will be divided into three parts:

1. In the patient-care area, a population geneticist will be employed to study the frequency of genetic problems in the state. When this study is under way the geneticist will be available for counseling of patients, their families, and doctors.

2. In the laboratory, Stanford scientists will investigate diseases in animals which are similar to those in humans, using techniques of biochemistry, physiology, and genetics.

One major question to be answered is why genetic diseases do not show up uniformly, but appear in mild and severe forms. Another puzzle

is why some patients have mild forms while others are severely afflicted. If information about these could be found, Dr. Kretchmer believes important contributions to patient care might be made.

3. Combined patient and laboratory analysis will also be undertaken using samples of patients' blood, urine, hair and nails. The scientists hope that these studies will reveal more about the mechanisms of specific diseases.

The three parts of the overall program will be coordinated to complement each other with the long-range aim of improving treatment and care, counseling, and teaching related to these diseases.

DIVISION OF CLINICAL SOCIAL WORK ESTABLISHED AT STANFORD MEDICAL SCHOOL

Dr. Daniel E. O'Keefe, until this summer chief of the Social Service Department of the 500-bed Clinical Center at the National Institutes of Health in Bethesda, Md., is chief of the new Division of Clinical Social Work in the Stanford University School of Medicine, Dean Robert H. Alway announced today.

The division is the first in the country with the aim of providing social work participation in all appropriate areas of the medical curriculum.

The new division will develop educational programs which stress the importance of social and emotional factors in the care of patients. Its work is expected to fit in with the emphasis on behavioral sciences in the new curriculum of the medical school.

Faculty and staff will also offer social service assistance to hospital and clinic patients at the Stanford Medical Center.

In addition to serving as chief of the division, Dr. O'Keefe holds the rank of associate professor. He began work late last month.

Dr. O'Keefe had held his post at N.I.H. since 1952. He was responsible for directing the medical and psychiatric social work in the Clinical Center, a 500-bed research hospital. His staff not only assisted patients but also collaborated in research carried on in the various medical disciplines and undertook independent research on the social and emotional aspects of long-term illness.

- more -

The new division chief is 46. He is married and has three children. He received his B.S. from the University of Dayton in 1936 and his M.S. in social work two years later from Catholic University in Washington, D.C. He received his Ph.D. from the University of Minnesota School of Social Work in 1955.

His professional experience includes service with the Veterans Administration, the Army Surgeon General and the U.S. Public Health Service.

He is a charter member of the National Association of Social Workers and was chairman of its Psychiatric Social Work Section from July, 1959, through June of this year.

STANFORD CLINICS RESUME SERVICES

FOR STUTTERERS

The Stanford University Speech and Hearing Clinic next week will resume group therapy sessions for adult stutterers.

The program is run throughout the year except during academic vacation periods, according to Dr. Virgil A.Anderson, director of the clinic.

Sessions for the stutterers will be held Tuesday nights from 7:30 to 9:00, beginning October 4.

The clinic is located in Edwards Building of the Stanford Medical Center, 300 Pasteur Drive, Palo Alto.

All interested persons are invited to attend, Dr.Anderson said. The program allows for some individual therapy if needed.

Dr.J.Douglas Noll is staff advisor for the stutterers, and Tom Shipp and Bruce Porch are the clinical assistants in immediate charge of the program.

Further information may be obtained by calling the clinic at DAvenport 1-1200, extension 5416.

INSTITUTE FOR CHILDHOOD APHASIA SCHEDULED

A mysterious malady which can isolate otherwise normal children in a world without language will be studied at the Institute on Childhood Aphasia, Sept. 19-21.

The Institute is sponsored by Stanford University School of Medicine, the California Society for Crippled Children and Adults, and the National Easter Seal Research Foundation. Closed sessions for the 30 participants will be held at the Stanford Medical Center during the first day of the conference and continue for two days in the Villa Hotel in San Mateo.

A meeting which will be open to the public will be held on Tuesday at 8:30 p.m. in the University of California Medical Center Auditorium in San Francisco. Three specialists will be panelists on the television show Doctors News Conference the same evening. The broadcast starts at 9:30 p.m. over station KTVU, Channel 2.

Childhood aphasia is a brain disorder which destroys the ability to reason abstractly. As a result of the ailment, speech and reading skills are lost or never acquired. The exact incidence of childhood aphasia is unknown since it is often confused with mental retardation and deafness.

Experts from the fields of medicine, psychology, speech pathology and audiology, special education and social work will meet to clarify the diagnosis, treatment and therapy for children who have been stricken with aphasia since birth. The experts will also try to identify areas where further research is needed.

--more--

General chairman for the Institute will be Dr. Robert West, director of the Speech Clinic at Brooklyn College, Brooklyn, New York. Participants will include Dr. Richard L. Masland, director of the Department of Neurological Diseases and Blindness, National Institute of Health, Bethesda, Md.; and Dr. Chester A. Swinyard from the Institute of Physical Medicine and Rehabilitation, New York.

Also taking part will be Dr. Mildred C. Templin, associate professor in the Institute of Child Welfare at the University of Minnesota; Miss Else Haeussermann (cq), Department of Pediatric Psychiatry, Jewish Hospital, Brooklyn; Dr. Nancy Wood, specialist in speech and hearing in the Department of Health Education and Welfare, Washington, D. C., and Dr. James Carrell, director of the Speech and Hearing Clinic at the University of Washington.

Other participants include Dr. Roman Jakobson from the Department of Slavic Languages and Literatures at Harvard University; Dr. Karl Pribram, associate professor of psychiatry at Stanford, and Dr. Lamar Roberts, chief of neurosurgery at the University of Florida College of Medicine.

Interest in childhood aphasia was raised in California recently when a group of parents of children who were suspected of being aphasic formed a state-wide organization. The group later joined the California Society for Crippled Children and Adults, which today is co-sponsoring the first such institute held in the United States.

Stanford University received a grant of $10,000 for the meeting from the National Easter Seal Research Foundation and an auxiliary planning fund of $1,500 from the New York Association for the Aid of Crippled Children.

An open panel discussion of medical care for the aged, jointly sponsored by the Palo Alto Medical Staff and Palo Alto-Stanford Hospital Resident Staff, will be held Thursday evening (Oct. 27, 1960) at 7 in Room M106 in the Stanford School of Medicine.

The discussion, which will be open to the public, will deal with the political and economic implications of the problem. It will be moderated by Dr. Clyde Boice, president-elect of the Santa Clara County Medical Society and vice chief of the Palo Alto Medical Staff.

Dr. Daniel J. Feldman, Associate Professor of Medicine and Director of the Rehabilitation Services at Stanford Medical School, and Joseph Donovan, Executive Secretary of the Santa Clara County Medical Society, will be principal speakers. Two members of the resident staff will complete the panel.

It will be the first of a series of projected meetings to discuss problems of interest to the medical profession and community.

"ARS MEDICA" EXHIBITION

SCHEDULED AT STANFORD MEDICAL CENTER

A unique collection of rare medical prints, including works by great masters, will be exhibited at Stanford Medical Center from October 9 to 22, it was announced today. The exhibit will be in the lobby of the Boswell Building where the Stanford Clinics are located, and will be open daily from 8 a.m. until 6 p.m.

The recently expanded exhibit now includes 134 original prints depicting the practice of medicine and pharmacy over the centuries. Among the latest additions to the collection are prints illustrating the treatment of the mentally ill as well as graphic representations of dreams and delusions. Included in the exhibit are works by Durer, Daumier, Goya, Hogarth, Raphael, Rembrandt, Schongauer and Titian. Rockwell Kent and Robert Riggs are among the contemporary artists.

Entitled "Ars Medica," or "The Healing Arts," the collection is owned by the Philadelphia Museum of Art. It is being presented by Smith Kline & French Laboratories, Philadelphia pharmaceutical firm, under whose grant the exhibition was assembled.

Carl Zigrosser, Curator of Prints for the Philadelphia Museum of Art, compiled the medical illustrations. His "pioneering of a new form of art education through the support of industry" was recently acknowledged by the Philadelphia Art Alliance when it presented him with its 1959 Medal of Achievement.

- MORE -

The original collection, exhibited for the first time in 1952, was made up of 15 panels, each containing from five to 12 prints. In this form it was shown in selected art galleries, museums and medical and related schools throughout the United States, Canada, Puerto Rico, England, Wales, Scotland and Ireland. Last April, the expanded collection, now totaling 21 panels, was premiered at the Philadelphia Museum of Art during the 115th annual meeting of the American Psychiatric Association.

Among the outstanding prints in the collection are Rembrandt's "Christ Healing the Sick;" Vesalius' "Ninth Plate of Muscles;" Winslow Homer's Civil War portrayal of the "Surgeon at Work During an Engagement;" Toulouse-Lautrec's lithograph of the ailing French President Carnot; Wechtlin's woodcut of "Cosmas and Damian," patron saints of the physician and apothecary, and Hogarth's engraving of the London insane asylum, "Bedlam Hospital."

STANFORD CLINICS RESUME SERVICES FOR HARD OF HEARING

The Stanford University Speech and Hearing Clinic next week will resume group instruction in lip reading for adults who are hard of hearing.

The program is run throughout the year except during academic vacation periods, according to Dr. Virgil A. Anderson, director of the clinic.

Lip reading classes are scheduled Wednesdays from 7:30 to 9:00 p.m., starting October 12.

The clinic is located in Edwards Building of the Stanford Medical Center, 300 Pasteur Drive, Palo Alto. Fees are nominal--$10 for the quarter.

All interested persons are invited to attend, Dr. Anderson said. The program allows for some individual therapy if needed.

The lip reading class is under the supervision of Miss M. Jo Eeckhout (cq); Miss Pat Beverly is the therapist who teaches the class.

Further information may be obtained by calling the clinic at DAvenport 1-1200, extension 5416.

Memo to Science Writers:

This is to call to your attention two interesting Stanford papers being delivered during the meeting of the American College of Surgeons in San Francisco next week.

1. This is the first full report on the technique developed by Richard R. Lower and Norman E. Shumway for transplanting another dog's heart in a recipient dog. In 10 operations, 6 of the recipient animals were kept alive for from 6 to 21 days by the functioning foreign heart.

Dr. Lower has been asked to a press conference by the ACS press people and will be on hand at 3 p.m. Sunday, Oct. 9, in the Hunt Room of the Fairmont, to answer questions. The story is for release to PM's of Monday.

2. This reports a method of cooling the brain so that more time will be available for brain surgery. The current estimate, based on experiments in dogs, is that this method would double the 15-minute interruption of cerebral blood flow now permissible for patients whose whole body has been cooled. Dr. Robert J. Boyd, one of the six authors, is to deliver the paper; Dr. John E. Connolly, the senior author, will also be willing to talk to reporters.

Information about this paper (see enclosed abstract) has been sent to Miss Sara Barr Cohen of the ACS at the Fairmont. If you wish to see Dr. Boyd or Dr. Connolly, Thursday morning before the paper is delivered, you might ask her to have him come to the press room.

FOR RELEASE TO AM'S OF
FRIDAY, OCTOBER 14, 1960

Abstract of a paper to be delivered at the American College of Surgeons Meeting
San Francisco --- Neurological Surgery

AN EXPERIMENTAL STUDY OF THE TECHNIQUE AND EFFECTS OF SELECTIVE BRAIN COOLING

John E. Connolly, M. D., F.A.C.S., Edmund J. Harris, M. D., F.A.C.S.,
David L. Bruns, M. D., John W. Smith, M. D., and Robert Boyd, M. D.

General body hypothermia is currently employed by neurosurgeons to allow interruption of the cerebral circulation for periods of time up to 15 minutes. Selective cooling of the brain to cerebral temperatures lower than those currently tolerated by the heart should allow significantly longer periods of cerebrovascular occlusion.

We have investigated this approach to date on 75 dogs. Brain cooling is carried out by shunting blood from the carotid arteries through a blood heat exchanger and back into a distal carotid artery. The brain temperature is reduced from 37°C. to 15°C. in 20 minutes. At the same time the body temperature is maintained at or near normothermic levels. We have found in the dog that the brain can be safely and rapidly cooled to cerebral temperatures of 15°C. and subsequently rewarmed without evidence of neurological damage. Experience has shown that carotid flow rates must be carefully regulated as the level of brain cooling is lowered to protect against brain damage.

To test the protective effect of selective brain cooling, the cerebral circulation must be completely occluded for varying periods of time after the desired brain temperature has been reached. We have found that the only successful method of accomplishing this in the dog has been by stopping the heart after the brain has been cooled to the desired level. Utilizing this method the length of time cerebral blood flow can be completely occluded without brain damage has been correlated with various brain temperatures. The clinical application of selective brain cooling should facilitate intracranial procedures by affording an avascular field for periods of 30 minutes or more.

PSORIASIS MAY BE DUE TO ALLERGIC REACTION, STANFORD SCIENTISTS DISCOVER

Patients who develop psoriasis, the disfiguring and incurable skin disease which afflicts 3 to 4 million Americans, may be allergic to some chemical in their systems, a team of Stanford University School of Medicine investigators reported today.

They said their findings offered a lead pointing to the fact that antibodies are formed in psoriasis. This means that a patient has been exposed to an antigen of some sort. Antigens stimulate the body to produce antibodies, one of the main defenses against disease.

On the basis of available evidence, the scientists inferred that psoriatic patients are allergic to something in their own systems. Researchers have attempted for decades to find a bacteria, virus or other outside agent which could cause the disease, but no such agent has been found.

Such allergy is called an autoimmune response. So far only a small number of human diseases have been implicated as being possibly autoimmune.

The Stanford research was reported in the November issue of the Archives of Dermatology. Authors of the paper were Dr. Muhammed Aswaq, Dr. Eugene M. Farber, Dr. Anthony P. Moreci and Dr. Sidney Raffel.

To detect the antibodies, the scientists used a procedure called the passive cutaneous anaphylactic (PCA) reaction. It is a very sensitive method of detecting antigen-antibody interactions.

Blood serum from a patient was injected between layers of a guinea pig's skin. Later, ground up skin from a psoriasis sore of the same patient was introduced into a vein of the pig. The skin "homogenate" was mixed with

--more--

a dye to aid in detecting the interaction.

In 81% of the 32 cases, interaction was observed at the site where the blood serum has been injected. The psoriatic skin homogenate had circulated throughout the pig's body, and reacted with a part of the blood serum.

Reaction was visible because the dye collected where the antigen-antibody combination had caused damage to the minute blood vessels of the skin.

Tests were also run using blood serum from patients with atopic dermatitis, an allergic eczema, and from persons without either disease. There was no reaction where those injections were made.

The research "points to the speculation that psoriasis may depend upon an autoimmune mechanism," the report states; "however, objective evidence for this possibility is not yet available."

The scientists are now preparing to try to identify the factors involved in order to learn more about the process.

The findings represent the culmination of seven years of investigation. Previous research failed to show results because specimens were not quick frozen and apparently deteriorated.

The research is part of a multidiscipline attack on psoriasis being undertaken by the Division of Dermatology with a $295,928 grant from the John A. Hartford Foundation, Inc., of New York.

Psoriasis is a chronic disease characterized by the eruption of round red patches covered by unsightly white scales--chiefly on the elbows, knees, scalp and back. It has been estimated that it affects as much as 2 per cent of the world's population.

Dr. Seymour Kolko, assistant professor of psychiatry in the Stanford University School of Medicine, has been named assistant dean for student affairs in the medical school.

Dr. Kolko is in charge of student standing and promotion as well as applications for internships and residencies. His appointment was effective late last month.

Student affairs were previously handled by Associate Dean Lyman M. Stowe, who is still responsible for academic affairs.

Commenting on the appointment, Dean Robert H. Alway of the medical school said: "Dr. Kolko was appointed to this position because of his deep interest in the students and their concerns. He has demonstrated this interest in many ways and we want the students to obtain the full benefit of it."

Dr. Kolko has been a member of the Student Standing and Promotions Committee for the last two years.

A 1945 graduate of Stanford, Dr. Kolko received his M.D. from the medical school four years later. He served his residency at the Veterans Administration Hospital in Menlo Park. He was a psychiatrist for the Air Force from 1951-53.

He joined the Stanford faculty in 1955 as an instructor while carrying on a private practice in psychiatry in San Francisco, but he is no longer in private practice. Dr. Kolko's special field is psychiatric rehabilitation and he has been a consultant for the San Francisco branch of the California Vocational Rehabilitation Services since 1955.

He is a member of the National Rehabilitation Association, American

STANFORD MEDICAL SCHOOL NAMES NEW FACULTY MEMBERS

Four associate professors and two instructors have been named to the full-time faculty of the Stanford University School of Medicine, Dean Robert H. Alway announced today.

A new member of the voluntary faculty is Dr. E. Dwight Barnett, former administrator for the Palo Alto-Stanford Hospital Center. Dr. Barnett is serving as clinical professor of administrative medicine in the Department of Preventive Medicine for this academic year.

He was administrator of the Hospital and professor of hospital administration in the Medical School from 1958 until his resignation last June. Dr. Barnett had been professor of administrative medicine at Columbia University from 1952 to 1958.

Two of the appointments to associate professor were effective Jan. 1. Dr. Kao Liang Chow was appointed associate professor of medicine (neurohistochemistry), and Dr. William van Bogaert Robertson was named associate professor of biochemistry in the Department of Pediatrics.

Dr. Chow had been associate professor of physiology at the University of Chicago since 1954. He earned a B.A. from Yenching University, Pekin, China, in 1943 and a Ph.D. from Harvard in 1950.

He was a research assistant at the Yerkes Laboratories of Primates under the former director and leading neurophysiologist Dr. Karl Lashley. Dr. Chow has become a major contributor to the literature of the rapidly-growing field of neurophysiology.

Dr. Robertson's major role at Stanford is as director of the laboratories and research program at the Stanford Convalescent Home. He had been

---more---

professor of biochemistry since 1952 and associate professor of experimental medicine at the University of Vermont College of Medicine since 1947. He was also consulting clinical chemist for DeGoesbriand Memorial Hospital.

Dr. Robertson received an M.E. degree from Stevens Institute of Technology in 1934 and a Ph.D. from Albert Ludwig University, Germany, in 1937. He has had extensive research experience as a biochemist.

Two other long-term appointments will be effective in early summer and at the beginning of the next academic year.

Dr. Ellis N. Cohen has been appointed associate professor of anesthesia starting July 1. He is presently associate clinical professor of anesthesiology at the University of Minnesota. He has been chief of the Department of Anesthesiology at Charles T. Miller Hospital, St. Paul, since 1949.

Dr. Cohen's research has dealt with problems of anesthesia at both the laboratory and clinical levels and he has written numerous articles on these topics.

European-trained pathologist Dr. Bruno Gerstl has been appointed associate professor of pathology beginning Sept. 1. He will be in charge of laboratory services in the Palo Alto Veterans Administration Hospital. Dr. Gerstl has been chief of laboratory service at Oakland Veterans Hospital and and assistant clinical professor of pathology at the University of California since 1947.

He received his M.D. in Vienna. He was a research assistant and instructor at Yale from 1941 to 1944 and then director of the Central Laboratory of Pathology and Research for the State of Connecticut from 1944 to 1947.

Beside Dr. Barnett's appointment, two other short-term appointments were made: Dr. Alfred D. Surtees as instructor in anesthesia, and Dr. Robert H. Sagerman as instructor in radiology. Educated at London University, Dr. Surtees is presently assistant anesthetist at Massachusetts General Hospital and instructor in anesthesia at Harvard Medical School. Dr. Sagerman is a resident in radiology at Montefiore Hospital in New York City.

NOTE TO EDITOR: This story is timed for release following presentation of a research report by the authors at the annual meeting of the Western Association of Physicians at Carmel, Calif.

FOR RELEASE TO A.M. PAPERS OF SATURDAY, JANUARY 28, 1961.

WARNING TO MOUNTAIN CLIMBERS: WATCH OUT FOR "PNEUMONIA"

CARMEL, Calif.--Many classic cases of fatal "pneumonia" among mountaineering parties were probably nothing of the sort, a Stanford University School of Medicine specialist in lung and heart ailments reported yesterday.

Instead they were very likely a little understood but more easily corrected condition which literally drowns its victims--ironically because of lack of oxygen.

The condition, called high altitude pulmonary edema, was the subject of a report by Stanford Associate Professor of Medicine Herbert N. Hultgren. He generally finds time for two or three mountain climbing trips himself each year.

Co-authors of the paper were Dr. Warren S. Spickard, associate clinical professor at the University of Washington School of Medicine; Dr. Charles S. Houston of the Aspen Clinic, Aspen, Colorado; and Dr. Kurt O. Hellriegel, medical director of Chulec General Hospital, La Oroya, Peru.

They urge all mountaineers doing extensive climbing above 10,000 feet to be aware of acute high altitude pulmonary edema and to prevent it by gradual acclimatization. Where a rapid descent to a lower elevation is not possible, oxygen should be carried for treatment.

Pulmonary edema is the movement of fluid from the blood into the air sacs of the lungs. The fluid acts like a mixture of salt water and egg white. It froths up when the patient breathes and can quickly "drown" him.

--more--

Apparently the condition occurs because of lack of oxygen. It follows rapid exposure to altitude (above 10,000 feet) without prior acclimatization, but is not like "mountain sickness". Nearly everyone going to high altitudes experiences mountain sickness at first, Dr. Hultgren says, with its symptoms of weakness, labored breathing, headaches, and loss of appetite.

Few people get pulmonary edema, but those who do may be in danger of dying unless properly treated. Major symptoms are a persistent cough, shortness of breath following the slightest exertion, a gurgling noise in the chest, and coughing up blood-streaked sputum.

These signs resemble those of pneumonia, but the chills and fever of pneumonia are not found when edema occurs. When chills or fever do occur, they may be due to an accompanying infection.

When signs of pulmonary edema occur, three steps should be taken promptly: the patient should be removed to lower altitude; oxygen should be administered continuously; the patient should be given absolute bed rest. Recovery usually is complete within 24 to 48 hours.

Dr. Hultgren and his co-workers have thoroughly checked medical and mountaineering publications to identify cases of pulmonary edema among mountain climbers, and have located six occurring in the continental United States. Most cases, however, have been observed in Peru where one can very quickly reach altitudes of over 14,000 feet.

But records are not often complete on persons who died high in the mountains without a doctor in attendance. The research group feels certain many deaths ascribed to "pneumonia" were due to edema.

Recent advances in the treatment of high blood pressure will be reviewed by faculty members of the Stanford University School of Medicine Saturday at a postgraduate conference for physicians, it was announced today by Associate Dean Lowell A. Rantz.

Known to doctors as hypertension, high blood pressure affects about 20 per cent of the adult population in the United States. Heart and circulatory ailments are the leading cause of death in the country, and hypertension and coronary artery disease are the commonest causes.

The conference will be held at Stanford Medical Center from 8 to 5 in room M 104.

Chairmen of the four sessions will be Dr. Halsted Holman, executive head of the Department of Medicine and Guggenhime (cq) Professor of Medicine; Dr. David Rytand, Bloomfield Professor of Medicine; Dr. Alfred Spivack, clinical teaching assistant in medicine; and Dr. John K. Lewis, professor of medicine.

Other faculty members taking part will be Dr. E. William Hancock, Dr. Herbert N. Hultgren, Dr. Gerald M. Reaven, Dr. John Young, Dr. Roy B. Cohn and Dr. Arthur Selzer. Dr. Dorothee (cq) Perloff, clinical instructor in medicine at the University of California School of Medicine, will also be a speaker at two of the sessions.

STANFORD CLINICS RESUME SERVICES

FOR STUTTERERS

The Stanford University Speech and Hearing Clinic next week will resume group therapy sessions for adult stutterers.

The program is run throughout the year except during academic vacation periods, according to Dr. Virgil A. Anderson, director of the clinic.

Sessions for the stutterers will be held Tuesday nights from 7:30 to 9:00, beginning January 10.

The clinic is located in Edwards Building of the Stanford Medical Center, 300 Pasteur Drive, Palo Alto.

All interested persons are invited to attend, Dr. Anderson said. The program allows for some individual therapy if needed.

Dr. J. Douglas Noll is staff advisor for the stutterers, and Tom Shipp and Bruce Porch are the clinical assistants in immediate charge of the program.

Further information may be obtained by calling the clinic at DAvenport 1-1200, extension 5416.

LIBRARY COLLECTION TO BE DEDICATED TO THE MEMORY OF DR. WILLIAM H. NORTHWAY

The library collections in physical medicine and rehabilitation of the Stanford University School of Medicine are to be expanded and dedicated to the memory of Professor William H. Northway who died last Dec. 23, Dean Robert H. Alway announced today.

During 30 years on the Stanford faculty, Dr. Northway devoted his professional life to physical medicine. He served as chief of the outpatient clinic, assistant dean of the School of Medicine, and acting superintendent of Stanford University Hospital in San Francisco.

At the time of his death, Dr. Northway was chief of physical medicine of Palo Alto-Stanford Hospital Center. In recent years his particular interest in his field had been in rehabilitation of polio patients. His clinical papers on the subject were widely published.

Since undergraduate days, Dr. Northway had been continuously at Stanford, and his three sons and his brother have all attended the University.

Contributions to the William H. Northway Memorial Book Fund should be sent to the Dean's Office, Stanford School of Medicine, Stanford Medical Center, 300 pasteur Drive, Palo Alto, California.

STANFORD DEAN TO ASSIST VENEZUELAN MEDICAL FACULTY

Dean Robert H. Alway of the Stanford University School of Medicine will be in Caracas, Venezuela, Friday through Tuesday (Feb. 24-28) consulting with members of the faculty of the Central University of Venezuela regarding development of a new medical school in that city.

Dr. Alway said that his hosts are seeking information on Stanford's experience in reorganizing a medical school and increasing its role in research.

In many ways the medical school of the Central University resembles Stanford's before its move to the campus two years ago. The faculty members spend about as much time in private practice as in teaching. In addition, Central University is a state school and must accept all candidates for admission, whether they are qualified or not.

Some of the Venezuelan physicians would like to establish another school at the Vargas Hospital along the lines of the Stanford plan and with stricter admission policies, the dean said. He does not plan to recommend a specific program but will outline the general needs and problems if they are to establish such a school.

The dean's invitation grew out of an earlier visit to Caracas by Dr. Eugene M. Farber, professor of medicine and head of Stanford's dermatology division. Dr. Farber was a visiting professor there last summer, at which time he reported on the new Stanford curriculum which went into effect in September, 1959.

Dean Alway was invited by Professors F. Ruben Coronil, Otto Lima Gomez and Francisco Montbrun. Mrs. Alway will accompany him also as their guest.

(Mailed Feb. 21, 1961) #######

$35,750 AVALON FOUNDATION GRANT TO STANFORD SCHOOL OF MEDICINE FOR PEDIATRIC PROGRAM

The Avalon Foundation has given the Stanford School of Medicine a grant of $35,750 to set up a visiting professor program in the Department of Pediatrics.

The Foundation was established in 1940 by Mrs. Ailsa Mellon Bruce, the first wife of David Bruce, the newly appointed ambassador to England. It provides grants primarily in the fields of health, medicine and projects pertaining to the development of youth.

Dr. Norman Kretchmer, head of the Department of Pediatrics, has recently invited four outstanding men in the field of pediatrics to take part in the program.

Participating is Dr. Allan M. Butler, director of clinical services at the Metropolitan Hospital in Detroit and former professor of pediatrics at Harvard.

Dr. Sam Z. Levine, professor of pediatrics at Cornell University Medical College, will be at Stanford during late March.

Dr. John Lind and Dr. Leo Kanner will participate in the program during June. Dr. Lind is professor of pediatrics at Karolinska Sjukhuset, University of Stockholm, Sweden. Dr. Kanner is professor emeritus of child psychiatry, Johns Hopkins University, and honorary consultant for its hospital.

Each visiting professor will have an office, a laboratory and living quarters near campus. He will spend the time in residence in the Department of Pediatrics, taking part in its educational and clinical activities.

STANFORD MEDICAL SCHOOL NAMES NEW FACULTY MEMBERS

Five men have been named to the full-time faculty of the Stanford University School of Medicine, Dean Robert H. Alway announced today.

Among those appointed was Dr. Thomas A. Stamey, who will be associate professor of surgery and chief of the Division of Urology in the Department of Surgery. His appointment will be effective July 1.

Dr. Stamey has been associate professor of urology at The Johns Hopkins University Medical School since last year and chief of urology for the Baltimore City Hospitals since 1958. He received his A.B. from Vanderbilt University in 1948 and his M.D. from Johns Hopkins in 1952.

Dr. Tag Eldin Mansour, associate professor in the Department of Pharmacology at Louisiana State University, has been appointed associate professor of pharmacology, effective April 1. He was recently awarded a five-year U.S. Public Health Service Senior Fellowship.

A native of Belkas, Egypt, Dr. Mansour graduated with honors from the University of Cairo in 1946 and received his Ph.D. in pharmacology from the University of Birmingham, England, in 1949. He was a Fulbright Fellow and instructor in physiology at Howard University from 1951 to 1952.

Dr. William M. Gilmore, Jr., was named assistant professor of pediatrics (physical medicine), effective last month. He had been

--more--

clinical instructor of medicine (physical medicine) at Stanford since 1958.

Since 1957 Dr. Gilmore had worked as director of rehabilitation services for the Stanford Convalescent Home and medical director of the Easter Seal Society of Alameda County Rehabilitation Center.

Short-term appointments included: Dr. Irwin A. Schafer as instructor in pediatrics and Dr. Angelos Dellaporta as acting instructor in surgery (ophthalmology); also Dr. Kirk H. Prindle as clinical assistant professor of surgery and Dr. Daniel W. Meub, clinical instructor in surgery.

Dr. Schafer is presently a research fellow in the Departments of Preventive Medicine and Pediatrics at Harvard Medical School. He will join the Stanford faculty in July. Dr. Dellaporta has been a research associate and clinical instructor in surgery (ophthalmology) at Stanford since 1958.

BIOLOGICAL PHOTOGRAPHERS ASSOCIATION TO HOLD MEETING

A breed of photographers interested in the human form divine, but less in its cheesecake possibilities than in its bone-skin-and-hair detail, will get together at the Stanford Medical Center, February 17-19.

These are members of the Biological Photographers Association who will be holding their third Western States Regional meeting under the sponsorship of their Northern and Southern chapters. The Association is the only professional society in North America dedicated to the advancement of the skills of medical and biological photography. Its world-wide membership includes physicians, medical editors, educators and photographers in the field of medical and other biological sciences.

In conjunction with the three-day meeting, there will be a display of prints by Association members in the Student Lounge of the School of Medicine building, Stanford Medical Center. Among the prints is one of a fossil seashell smaller than a pinhead and magnified 750 times by a new technique of multiplane focus and photomicroscopy. The new process that produced this startlingly detailed, sharp print will be described during the meeting.

To open the three-day meeting on Friday evening, February 17, there will be a showing of medical and biological motion pictures.

A full day of activities is planned for Saturday, February 18, starting at 9:00 a.m., to which the public is invited. Seven papers will be presented in the course of the day. Among these will be one on "Visual Communication" by Verlin Yamamoto, F.B.P.A., chief of medical illustration of the Veterans' Administration Hospital in Des Moines, Iowa, and national president of the Biological Photographic Association.

A clinical workshop of photographic techniques will be held at 3:30 under moderator Howard Tribe of the University of Utah. Luncheon and refreshments will be served during the all-day Saturday session.

FLEISCHMANN FOUNDATION GRANTS $767,000 TO MEDICAL SCHOOL

The Max C. Fleischmann Foundation of Nevada has given Stanford University a grant of $767,000 to complete construction and purchase of equipment for the Basic Medical Sciences Laboratories of the School of Medicine, University President Wallace Sterling announced today.

The new grant brings to $1,192,000 the contribution from the Foundation for the laboratories and covers their whole cost. The laboratories will be named "The Max C. Fleischmann Laboratories of the Basic Medical Sciences."

"We particularly appreciate the Foundation's generosity in providing these facilities," Dr. Sterling said, "because they are at the heart and core of Stanford's new program of education for medicine."

President Sterling referred to the Stanford Plan of Medical Education which went into effect in the fall of 1959, at the same time the School of Medicine was moved from San Francisco to the University campus.

The laboratories are the "home base" of medical students for the first three years they are at Stanford. To avoid the splintering of courses found in many schools, much of the work is taught cooperatively by six departments.

More equipment is available in these laboratories than could be provided in any single departmental laboratory, and it may be used by students who wish to explore their special interests more deeply. The facilities have already produced a substantial increase in the amount of student research conducted.

--more--

The curriculum also allows time for students to pursue interests outside of medicine by taking courses elsewhere in the University. The overall aim is to educate physicians who are more aware of the broad range of human needs.

The Fleischmann Foundation is a testamentary trust established to carry out the philanthropic wishes of the late Major Max C. Fleischmann, a long-time resident of Nevada.

The foundation earlier contributed $425,000 to the University for the laboratories in a series of gifts between 1956 and 1959.

The latest gift qualifies Stanford for an additional $255,666 under the terms of a recent Ford Foundation grant to the University. Stanford has to produce three gift dollars to earn one dollar from the Ford award. This additional money may be used for any University need.

MEDICAL SCHOOL ENDS EXECUTIVE REORGANIZATION WITH PSYCHIATRY APPOINTMENT

Dr. David A. Hamburg will become professor and executive head of the Department of Psychiatry of the Stanford University School of Medicine on Aug. 1, Dean Robert H. Alway announced today.

Dr. Hamburg, 35, is now chief of the Adult Psychiatry Branch of the National Institute of Mental Health in Bethesda, Md. He is an authority on the effects of psychological stress upon human behavior, particularly among high school and college students.

He is the last executive to be appointed in the reorganization aimed at making the medical school an integral part of the University. Until one and a half years ago most of the medical instruction was carried on in San Francisco. Dr. Hamburg is the sixth new department head since Dr. Alway became dean in 1957.

"We now have the departmental executives to provide the leadership for putting into full effect the Stanford Plan of Medical Education, developed and adopted by the faculty in 1958," Dean Alway said. "Dr. Hamburg will be particularly valuable in making the most of Stanford's strengths in the behavioral sciences and in medicine."

The new curriculum, spanning five years, leaves free time for students to pursue academic interests in addition to medicine. The aim is to educate doctors who are more aware of the broad range of human needs.

--more--

The new executive succeeds Dr. Thomas A. Gonda. "As acting head of the department for the last three years," Dean Alway said, "Dr. Gonda has played an invaluable role in furthering the development of both the psychiatric program and the medical school."

Dr. Gonda will be on sabbatical leave next year at Oxford University, Oxford, England, and then will return to his post as associate professor at Stanford.

Dr. Hamburg's research has fallen in two major areas. He has investigated effects of psychological stress on the function of the adrenal and thyroid glands. He has also studied human behavior under stress, especially the ways in which normal individuals cope with very difficult situations.

Dr. Hamburg has held his present post since 1958. He was a fellow at the Center for Advanced Study in the Behavioral Sciences, located in the foothills behind the Stanford campus, in 1957-58.

Before that he was assistant director, then associate director, of the Institute of Psychosomatic and Psychiatric Research and Training, Michael Reese Hospital, Chicago.

He received his A.B. and M.D. degrees from Indiana University where he was elected to the undergraduate and medical honorary societies Phi Beta Kappa and Alpha Omega Alpha.

He received his professional training at Michael Reese Hospital, Yale University and the Institute for Psychoanalysis in Chicago.

Dr. Hamburg's wife, Betty, has an M.D. degree from Yale and is also trained as a psychiatrist. The couple now lives at 4836 Drummond Ave., Chevy Chase, Md.

STANFORD MEDICAL STUDENTS SUFFER HUNGER AND COLD FOR EXPERIMENT

What happens to a man suddenly dropped from the sky in the Arctic winter and left to fend for himself? What mental and physical tortures can he stand before he reaches the end of his tether? How long can he live without food?

A research team from the Department of Physiology of the Stanford University School of Medicine last month spent five days camped on a frozen Alaskan river in an attempt to get some of the answers to these questions for the Air Force. Included in the group were three medical students who, as subjects in the experiment, learned about Arctic survival at firsthand.

They can testify that a downed flier will get very irritable after a couple of days--so much so he may squabble with a good friend over the supply of firewood, even though trees are all around.

His mind will skip about from subject to subject, even though he may try to put his free time to good use.

He will do useless tasks like making a fire he doesn't need. (His clothing is so well insulated that heat cannot penetrate.) As fourth-year student Charles C. Jenkins of Piedmont put it, "A fire keeps you busy and makes you feel good." His classmate, Henry F. Davis of Susanville, Calif., added: "With a fire you feel you can master the elements."

Most important, however, is the matter of food. Though their stomachs sometimes seemed to be tied in knots, the six subjects found that

--more--

starving for five days did them no real harm. They lost an average of about 12 pounds each, but quickly gained the weight back afterwards. They learned a man could live on nothing but melted snow if he had the sense to conserve his energy.

Interesting as these impressions may be, they are only by-products of the study. The trip was really arranged to allow Stanford physiologists to conduct a careful scientific experiment.

The experiment was carried out on the Chena River at the Air Force's Arctic Aeromedical Laboratory. The laboratory is located at Fort Wainwright (formerly Ladd Field) near Fairbanks.

As planned by Assistant Professor Terence A. Rogers, one objective was to determine the exact energy cost of living in this hostile environment. From this information Dr. Rogers hopes to predict the likely survival time of a starving man in the Arctic. Obviously such knowledge would be of vital interest to the Air Force.

Other purposes were to learn more about the dehydration which accompanies cold exposure and starvation, and about the psychological deterioration of the subjects.

Rogers, Jenkins and Davis were three of the subjects. Vance Israel, a first-year student from Palo Alto, and two Air Force men, T/Sgt. William Hommel and S/Sgt. Milford Baugh, also camped on the ice.

Professor Ronald Grant of the Physiology Department, John Klopping, cinefluorography technician in Radiology, and James Setliff, Rogers' research assistant, made up the support crew.

While the "icemen" rested in their shelters, the support crew had to work night and day. They serviced the devices which measured oxygen consumption, carried specimens to the field laboratory and did necessary analyses for the experiment.

--more--

The scientific findings of the project will not be ready for several weeks. But the students, two of whom used part of the free time in the medical curriculum to make the trip, have learned the value and difficulties of research carried out in the field.

And they learned a great deal about the capacity of the body to withstand physical and emotional strain. Two suffered from frostbite and found their feet still extremely sensitive two weeks after their ordeal was over.

They also found out what five days of starvation can do to a man's hunger. Davis gained 13 pounds in 27 hours. Israel reported having "an immorally huge appetite. I ate until I was full and my palate still craved the eating experience," he said. "From now on I'll have a little more sympathy with compulsive eaters."

AIR FORCE RESERVISTS TRAIN IN PALO ALTO-STANFORD HOSPITAL

One weekend each month about 50 Air Force Reservists come to the Palo Alto-Stanford Hospital Center and exchange their blue uniforms for the white garb of hospital orderlies. The men, members of the 44th Casualty Staging Squadron, are learning to be medical technicians.

The Palo Alto-Stanford Hospital is the only non-military hospital in California providing such instruction for the Air Force. Three other reserve units are training in military hospitals at bases in the state.

The squadron, stationed in San Jose, began training in the hospital the first weekend of January. The men will take a total of 12 to 13 weekends of intensive orientation comparable to that received by hospital orderlies.

"It is our responsibility to offer our teaching as well as our medical facilities to other community agencies. This is another example of the potential for community service in a teaching hospital," Mrs. Darlene Lutts, director of Nursing Service, said.

The casualty squadrons are being trained to receive wounded from the battlefield in time of war and to administer medical care until the wounded can be airlifted out of the area. All members of this squadron received some medical instruction during basic training.

Half of the squadron attends classes and works in the hospital on the first Saturday of each month and the other half on the first Sunday. On the alternate weekend day, the groups attend classes in medical care in the Air Force Reserve Center at 40 N. Fourth St., San Jose.

--more--

The men are being trained in the medical, surgical and pediatrics units in the hospital as well as in the Emergency Room, Operating Rooms and Central Services Department, which distributes medical and surgical supplies.

They will undertake everything from routine patient care, such as lifting and moving a patient, to the more complex isolation techniques and preoperative and postoperative care. They will have a chance to observe at firsthand surgical techniques and the administering of medications to patients.

On completing the weekends of orientation, reservists will continue working in the hospital as orderlies on the same weekend-a-month schedule until their reserve duty is completed--in come cases a period of four or five years.

Lt. Col. John Anderson of the Palo Alto Medical Staff is commander of the squadron and Capt. Ralph Allison, a resident in psychiatry in the hospital, is medical training officer. Capt. Ira Sherwin, also a resident in psychiatry, and Capt. Harlow Standage of Aptos, Calif., are instructors in the program.

Four registered nurses in the squadron, as well as head nurses in the hospital, supervise the men during their training periods.

SCIENTIST NAMED PROFESSOR OF NEUROLOGY AT STANFORD

Dr. Frank Morrell, a leading American neurologist, has been appointed professor of medicine and head of the division of neurology at Stanford University School of Medicine, Dean Robert H. Alway announced today.

Dr. Morrell, 34, is former associate professor of neurology and neurophysiology at the University of Minnesota. In addition to holding the faculty post at Stanford, he is executive of the division of neurology for Palo Alto-Stanford Hospital Center.

Dr. Morrell is widely known for his studies of epilepsy and for basic research on the molecular basis of learning. Recently he has investigated the mechanism by which single nerve cells in the brain receive and store information. His work offers the first concrete evidence for the current theory that memory is the imprinting of a code on complicated molecules of a chemical called ribonucleic acid (RNA).

Dr. Morrell succeeds the late Dr. Henry Wise Newman as head of the division. Dr. Newman, who died in 1959, was an authority on multiple sclerosis and had conducted fundamental studies on the effects of alcohol on the human body.

Dr. Morrell was educated at Columbia University, where he received his A.B. and M.D. degrees. He also holds an M.Sc. degree from McGill University. He received training at Montefiore Hospital in New York City, National Hospital, Queens Square, London, and the Montreal Neurological Institute.

At Montreal, Dr. Morrell was associated in research with Dr. H. H. Jasper, and Dr. Wilder Penfield.

He was at Minnesota from 1955 until moving to Stanford last month. He is married and has three children. The family lives at 536 Gerona Rd., Stanford.

NONTECHNICAL ABSTRACT OF PAPER TO BE PRESENTED AT THE ATLANTIC CITY MEETING OF THE FEDERATION OF AMERICAN SOCIETIES FOR EXPERIMENTAL BIOLOGY, 1961

SUBJECT: INDIVIDUAL DIFFERENCES IN SENSITIVITY OF PEOPLE TO THE CENTRAL EFFECTS OF CAFFEINE.

AUTHORS: Avram Goldstein, M.D., and Richard Warren. (Dr. Goldstein is professor and executive head of the Department of Pharmacology. Mr. Warren is a medical student.)
ADDRESS: Department of Pharmacology, Stanford University School of Medicine, Palo Alto, Calif.

ATLANTIC CITY ADDRESS: Hotel Dennis.
TIME: 10:15 a.m., Monday, April 10.
PLACE: St. Dennis Room, Hotel Dennis.
PROGRAM: American Society for Pharmacology and Experimental Therapeutics.

FOR RELEASE TO P.M.'S
APRIL 10, 1961

Caffeinated beverages like coffee and tea are widely drunk and it is supposed that people derive a stimulant effect from the caffeine. This effect is variously described as "pepping one up", "making one more alert", and so on. Many people claim that when they drink coffee in the evening they cannot fall asleep easily. Others claim that coffee doesn't bother their sleep at all. Moreover, there are very great differences between people with respect to the daily amount of caffeine intake, from none at all to ten cups of coffee (or more). The purpose of our investigation was to learn more about the nature of the differences in sensitivity to caffeine and the relationship of these differences to the caffeine habit. Is it true that people differ as much as they claim in their responsiveness to a given dose of caffeine? If so, what is the cause of the difference? And what connection is there between caffeine sensitivity and caffeine habit?

--more--

The results being reported at this time concern the effects of caffeine upon sleep. The findings show that approximately 20 per cent of the subjects were always kept awake by caffeine and 20 per cent were never kept awake by it. (See below for further details.) The implications of the results have more significance than might be indicated by a study of the effects of coffee. They suggest that an individual's response to a drug such as caffeine could be genetically determined, although this hypothesis has not been tested yet. If this hypothesis proved correct, it would have useful applications in medical practice; it might also shed new light on the problems of drug addiction and alcoholism.

Over a period of several years, unselected groups of medical students have been given a fixed dose of caffeine about an hour before bedtime, after abstaining from caffeine for ten hours or more. To minimize subjective bias the experiments were done on a "double-blind, placebo-controlled" basis. This means that subjects were given decaffeinated coffee which sometimes had added to it 150 milligrams of caffeine (the usual amount in a strong cup of coffee) and sometimes lactose powder. It had been shown, in a special set of experiments, that subjects were not able to distinguish by taste or appearance between a sample containing caffeine and a placebo containing lactose. All samples were coded by random serial number, and the person who distributed the samples did not have access to the code until the experiment was completed.

On the morning after taking each experimental sample, the subject filled out a questionnaire, reporting whether he had difficulty falling asleep, whether he slept as soundly as usual, whether he dreamed, whether he felt as well rested as usual on awaking. The experiment was repeated on several different nights with each subject.

--more--

Although different groups of medical students were subjects and the experiments were performed in different years, the results were remarkably consistent and definitive. Considering the entire group of subjects (approximately 300 students), it is clear that caffeine, taken in this dose and under these conditions, does delay the onset of sleep. It may also disturb the soundness of sleep, although this is not proved beyond doubt. It does not increase the frequency of dreaming, nor does it alter the subject's estimate of the refreshing quality of his sleep. About 20 per cent of the subjects always was kept awake by the caffeine but never by the placebo. Another 20 per cent was never disturbed by either caffeine or placebo. The others had variable responses.

Of great interest was the wide difference in responses among the subjects. Some few were so affected by the caffeine that they were unable to fall asleep for hours; others were but slightly disturbed; yet others were wholly unaffected. These evident differences led to a special series of experiments in which we attempted to segregate those who reacted consistently to caffeine from those who never reacted to caffeine. Twenty-two selected subjects participated in experiments of the kind described above, night after night, for 12 nights. During this period each subject received, in random order, six caffeine samples and six placebo samples. Seven subjects never reported difficulty falling asleep after a placebo, but reported difficulty on all six caffeine administrations; these we termed "reactors". Five subjects never reported difficulty falling asleep on any of the 12 nights. The remaining subjects, who gave variable responses, were not further considered.

--more--

The simplest hypothesis was now tested: that reactors absorb caffeine very well and therefore establish high blood levels (and brain levels) of caffeine, whereas non-reactors absorb caffeine poorly and consequently have low blood and brain concentrations. Five reactors and five non-reactors were given 300 milligrams of caffeine in decaffeinated coffee. Blood samples were then analyzed for caffeine at intervals, for three hours. There was absolutely no difference between the reactors and non-reactors. Both groups absorbed caffeine rapidly and completely, established the same blood levels, and eliminated caffeine at the same rate. The hypothesis is therefore rejected. At the same blood caffeine concentration, one person is stimulated by the drug, another is not.

Among the heavy coffee-drinkers there was a disproportionately large number of non-reactors. It is impossible to say whether this means that people become tolerant of the effects of caffeine when they take it frequently, or that non-reactors have to drink more than other people to get the same stimulant effect.

We are continuing these studies with the aim of learning more about the differences between reactors and non-reactors, and the reasons why some people are habituated to caffeine while others are not.

These studies were supported by a grant from the Maxwell House Division, General Foods Corporation.

NOTE TO EDITORS: The following story is for release to P.M. newspapers of Monday, April 10. Time of release is set to follow presentation of a scientific paper on the findings at a meeting of the American Society for Pharmacology and Experimental Therapeutics.

ATLANTIC CITY, N.J., April 10--If coffee keeps you awake at night, don't blame your imagination--blame your body chemistry.

So show the preliminary results of a study of the effects of caffeine upon sleep, conducted by two investigators at the Stanford University School of Medicine. They reported on their research today at a meeting of the American Society for Pharmacology and Experimental Therapeutics.

Tests on more than 300 subjects over a period of six years have shown that approximately 20 per cent was always kept awake by caffeine and 20 per cent never was. The remaining 60 per cent was sometimes kept awake, sometimes not.

The implications of the research findings have more significance than might be indicated merely by a study of the effects of coffee. The findings suggest that an individual's response to a drug such as caffeine could be genetically determined, although this hypothesis has not been tested yet.

If this hypothesis proved correct, it might help explain why some patients respond to treatment with drugs while others do not respond as well. It might also shed new light on the problems of drug addiction and alcoholism, and whether some people are more prone to become addicted or alcoholic.

--more--

The tests were conducted by Dr. Avram Goldstein, professor and executive head of the Department of Pharmacology, and medical student Richard W. Warren. Subjects were given decaffeinated coffee which sometimes had added to it 150 milligrams of caffeine and sometimes a placebo (a drug with no effect).

The amount of caffeine that was used is the usual amount in a strong cup of coffee. Previous tests had shown that people are not able to detect by taste or appearance the difference between the samples containing caffeine or placebo.

The subjects drank their coffee samples about an hour before bedtime, after going without coffee or tea (which also contains caffeine) for at least 10 hours. The next morning they filled out questionnaires reporting how they had slept. They were tested up to 12 consecutive nights.

"Although different groups of medical students were subjects and the experiments were performed in different years," Goldstein and Warren reported, "the results were remarkably consistent and definitive. It is clear that caffeine, taken in this dose and under these conditions, does delay the onset of sleep for some people.

"It may also disturb the soundness of sleep, although this is not proved beyond doubt. It does not increase the frequency of dreaming, nor does it alter the subject's estimate of the refreshing quality of his sleep."

Another interesting finding was that among the heavy coffee drinkers tested there was a higher than average proportion of non-reactors. "It is impossible to say whether this means that people become tolerant of the effects of caffeine when they take it frequently," the investigators said,"or that non-reactors must drink more than other people to get the same stimulant effect."

The studies are continuing with selected "reactors" and "non-reactors"to find out what the difference is between the two groups.

Goldstein and Warren are trying to develop methods for telling the two types apart by testing their physical, mental and emotional reactions to caffeine. The investigators also want to learn the reasons why some people have the caffeine "habit" and others do not.

The research is supported by a grant from the Maxwell House Division, General Foods Corporation.

STANFORD FACULTY MEMBER NAMED MARKLE SCHOLAR IN MEDICAL SCIENCE

Dr. Stanley L. Schrier, assistant professor of medicine at Stanford University School of Medicine, has been appointed a Markle Scholar in Medical Science, it was announced today.

The appointment carries a $30,000 grant that will be paid to the medical school over a period of five years to support Dr. Schrier and to aid his research.

Dr. Schrier is one of 25 young medical scientists in the United States and Canada selected for the scholarship program by the John and Mary R. Markle Foundation of New York. He was the only California faculty member chosen.

The Foundation has made annual grants since 1948 to relieve the shortage of faculty members in medical schools and to strengthen medical education.

The Stanford scholar is 32 years old. He received his A.B. degree from the University of Colorado in 1949, and his M.D. in 1954 from Johns Hopkins Medical School.

He received additional training at Johns Hopkins Hospital, the University of Michigan Hospital and the University of Chicago Hospital. He joined the Stanford faculty in 1959.

Dr. Schrier's special field is hematology. In his current research he is studying the metabolism of the red cell wall. Metabolism is the process by which an organism produces energy for its vital functions.

Dr. Schrier and his wife, Peggy, have two daughters, Rachel, 5, and Leslie, 3. They live at 825 Ilima Court, Palo Alto.

ADMINISTRATOR NAMED TO DIRECT PALO ALTO-STANFORD HOSPITAL CENTER

Oliver E. Deehan has been named administrator of the Palo Alto-Stanford Hospital Center, President William R. Hewlett of the Hospital Board of Directors announced today.

Commenting on the appointment, Hewlett said, "Mr. Deehan took charge of the Hospital as acting administrator in a time of real crisis and has rebuilt public confidence in the institution. We are convinced he can provide the leadership that will bring the Hospital into the forefront among medical care centers in the nation."

Deehan succeeds Dr. E. Dwight Barnett, who resigned last June. He has been acting administrator since then.

Palo Alto-Stanford Hospital Center is the major patient care facility in the Stanford Medical Center, which also includes the Stanford University School of Medicine. The Hospital provides services for a large community in and around Palo Alto as well as for the medical school.

Deehan first joined the Hospital as associate administrator in 1957 and was promoted to deputy administrator in 1959. He received a B.S. degree from Columbia University in 1955, and an M.S. in hospital administration from Columbia's School of Public Health and Administrative Medicine in 1957.

He was in the U.S. Navy from 1946 to 1952 and during the last two years of service was a jet fighter pilot.

--more--

At 34 Deehan becomes one of the youngest administrators of a hospital in a major medical center in the United States. "The appointment is consistent with the dynamic atmosphere of the whole Medical Center," Hewlett said. "Many of Stanford's recent faculty appointees have also been highly qualified men in their thirties."

"Both his demonstrated performance and his leadership potential led us to choose him for this key job," the Board President said.

"In the last nine months Deehan and his staff have (1) markedly improved patient care and patient services; (2) placed the operation on a sound financial basis; (3) established a high level of employee morale; and (4) demonstrated ability to work successfully with both the private physicians of the Palo Alto Medical Staff and the faculty members of the School of Medicine."

Hewlett emphasized that there is every indication that the Hospital will meet its budget this year. Last year there was a large operating deficit that prevented its meeting certain financial obligations to the owners, the City of Palo Alto and Stanford University.

As current problems are brought under control, the Board feels Deehan will be able to consider the broader, long-range aspects of the Hospital Center's operation.

It feels he has the ability to carry through, with the Board's guidance, the programs necessary (1) to broaden the financial support of the Hospital, since it is clear that patients cannot be expected to bear the whole cost of facilities and services; (2) to provide the specialized care which a normal community hospital cannot afford; and (3) to provide, in conjunction with the Stanford School of Medicine, leadership in establishing Stanford Medical Center as the major center of medical care, medical teaching and medical research on the West Coast.

Deehan is married and has three children, Ellen, 7, Robert, 5, and Carol, 4. The family lives at 226 Solana Dr., Los Altos.

NOTE TO EDITORS: This story is timed for release following presentation of a research paper at 10:55 a.m. Friday.

FOR RELEASE TO P.M. NEWSPAPERS OF Friday, May 26, 1961.

HEAVY COFFEE DRINKERS FOUND PHYSICALLY DEPENDENT UPON CAFFEINE

Heavy coffee drinkers are inclined to have headaches and to feel sluggish and tired if they don't get their dose of caffeine in the morning, a Stanford medical student reported today (MAY 26) at the first Stanford/Medical Student Conference on the University campus.

The report by Richard Warren, who will receive his M.D. degree next month, was one of six presented today as examples of significant research being conducted by students in the School of Medicine.

Three of the papers were read by students in the first-year class, indicating that the new medical school curriculum which went into effect less than two years ago is encouraging research as the faculty had planned. These students did all or part of their work in the Max C. Fleischmann Laboratories of the Medical Sciences where they have a special opportunity to pursue their own interests more deeply.

Warren's research, done in cooperation with Dr. Avram Goldstein, professor of pharmacology, was based on detailed analysis of reactions of six heavy coffee drinkers who usually have five or more cups a day.

They did without their morning coffee, and then drank decaffeinated coffee containing either caffeine or a drug having no effect.

When they got caffeine this way, the subjects "tended to feel alert, talkative, jumpy, nervous, stimulated and more motivated to work," Warren said. "They tended to describe a feeling of well-being."

- more -

When the coffee contained the drug that had no stimulative effect, "subjects tended to complain of a headache" and to feel sleepy, sluggish groggy, tired, and depressed.

Careful tests beforehand with 50 coffee drinkers had shown that they could not distinguish the two beverages apart by taste or appearance.

Warren said that "withdrawal effects" are most prominent among the heaviest coffee drinkers. This study indicates that heavy coffee drinkers have physical dependence upon caffeine as shown by headache and mood changes when it is withdrawn.

The research was supported by a grant from the Maxwell House Division of General Foods, Inc.

OPEN HOUSE FOR SCIENCE STUDENTS TO FOLLOW DEDICATION OF LABORATORIES

An open house with a series of demonstrations of equipment used in the education of medical students will be held Saturday afternoon (MAY 27) from 1 to 4 p.m. at the Stanford Medical Center.

The open house will follow ceremonies at 11:30 a.m. marking the dedication of the $1,192,000 Max C. Fleischmann Laboratories of the Medical Sciences.

Demonstrations will be planned primarily to interest high school and college students who are considering careers in medicine or the biological sciences. Microscopes which can show living bacteria in motion, and an instrument which can simultaneously measure and record four types of information on body function (respiration, electrical waves in the heart, and so on) are among those to be shown in actual operation.

Displays and demonstrations will be set up in the Fleischmann Laboratories on the second floor of the Medical School Building in the Medical Center.

The entire cost of the student laboratories and the expensive equipment in them was paid for by the Max C. Fleischmann Foundation of Nevada.

Francis R. Breen of Reno, Nevada, a trustee of the Foundation, will take part in the dedication ceremonies, together with Dr. Wallace Sterling, president of Stanford University, and Dean Robert H. Alway of the Stanford School of Medicine.

- more -

There will be a brief discussion of "The Unity of the Medical Sciences" during the ceremony. Dr. Frederick A. Fuhrman, director of the laboratories, and two students will speak. The students are Lawrence T. Eschleman of Represa, California, and Michael A. Altman of Highland Park,Illinois, presidents of the classes of 1964 and 1965 respectively.

The two classes represented are the first to use the new laboratories, which were opened when the Stanford School of Medicine was moved to the campus from San Francisco in the fall of 1959.

The facilities are the "home base" of medical students for the first three years they are at Stanford. To avoid the splintering of courses found in many medical schools, some of the work is taught cooperatively by seven departments.

More equipment is available in these laboratories than could be provided in any single departmental laboratory, and it may be used by students who wish to explore their special interests more deeply. The facilities have already produced a substantial increase in the amount of student research conducted.

Students are assigned permanent places in the laboratories and may work there any hour of day or night. Professors come to the laboratories to teach the courses which are given before students begin assisting in the care of patients. In most schools the reverse is true--the students must use different facilities for each course.

The Fleischmann foundation was established by Max C. Fleischmann, former chairman of the board of The Fleischmann Company, originators of Fleischmann's Yeast. The company later merged with Standard Brands Incorporated.

The Foundation has continued to support the philanthropic organizations which interested Major Fleischmann. These ranged from educational institutions to health and youth services.

NOTE TO EDITORS: We are attempting to arrange a press conference with Dr. Rhoads Friday morning. Abstracts of the student papers will be mailed to science writers later this week.

MEDICAL CONFERENCE TO FEATURE STUDENT RESEARCH AT STANFORD

Six significant reports of scientific research conducted by medical students and a discussion of operations for cancer will highlight the first Stanford Student Medical Conference.

The conference will be held all day Friday (MAY 26) in Dinkelspiel Auditorium on the Stanford campus. Sponsors are the Stanford Student Medical Association and the Stanford Medical Alumni Association.

Student papers, some of which will be submitted for publication in scientific journals, cover such diverse topics as heavy coffee drinkers' physical dependence upon caffeine and the effect of high altitude on laboratory animals.

Three of the papers are by students who are just completing their first year of medical school. Selection of their papers indicates that the new medical curriculum which went into effect less than two years ago is encouraging student research as the faculty had planned.

These students did all or part of their research in the Max C. Fleischmann Laboratories of the Medical Sciences where they have a special opportunity to pursue their own interests more deeply. The laboratories will be dedicated Saturday morning (MAY 27). Saturday afternoon there will be an open house and demonstration of equipment in the laboratories.

The principal address will be given on Friday by Dr. Jonathan E. Rhoads, provost and chairman of the Department of Surgery at the University of Pennsylvania. He will speak on "Calculation of the Gains and Risks of Operations for the Prevention of Cancer."

- more -

On Friday afternoon members of the graduating class of 1961 will present details of a program of patient diagnosis and treatment from the wards of the Palo Alto-Stanford Hospital Center.

The purpose of the conference is to further the intellectual development of students, to demonstrate student accomplishments, to stimulate research by providing an outlet for communicating results of investigative projects, and to bring about closer relations with the alumni.

Medical student Donald J. Prolo of San Jose is chairman of the committee which organized the meeting. Augustus A. White III of Memphis, Tenn., president of the Stanford Student Medical Association, headed the research paper selection committee.

600 YEARS OF SERVICE HONORED BY HOSPITAL CENTER

Fifty-one employees of the Palo Alto-Stanford Hospital Center whose combined length of service comes to more than 600 years were honored at the Hospital Center's third annual Gold and Silver Award Banquet this week.

Administrator Oliver E. Deehan presented silver pins for 20, 15 or 10 years' service to 50 of the men and women.

In addition, Miss J. Marie Havneros, administrative assistant in the Nursing Service, received a corsage as the employee with the most experience in the Hospital. She first came to work for Palo Alto Hospital 36 years ago this month.

The employees' group includes William Gilmour of Menlo Park, a cook, and his wife, Vivian, who works in the laundry. Gilmour started work in the Hospital 13 years ago. A year and a half later he got his wife a "temporary job" there but it turned into a regular career for her.

This was the first time 10-year pins were awarded, so some employees in that group actually have worked at the Hospital for more than that amount of time.

Principal speaker for the banquet, given at Rickey's Studio Inn, was Gordon P. Smith, vice president of the Board of Hospital Directors, who discussed "The Challenging Future of the Medical Center."

Employees who received awards are as follows:

Katharine O'Hair of Administration and Lura Robles of Laundry, both from Palo Alto, silver 20-year pins.

- more -

Nursing Service's Gertrude Edwards of Menlo Park, Kathryn McPhail of Palo Alto, and Verla Martin of Mountain View, for 15 years of service.

Forty-five 10-year silver pins went to the following:

From PALO ALTO: Naomi Kincaid, Virginia Graves, Jennie Duarte, Myrtle Hanson, Clare Mynderse, and Etty Huynen of Nursing Service; O. Denzel Braden and Anona Koehler of Operating Rooms; Hazel Tierce and Marien Cunningham of Business Office; Blanche Freeman of Communications; Virginia Howe of Admitting; Peteris Strautnieks and Ida Lausten of Housekeeping.

From MENLO PARK: Nadine Whiteaker, Peggy Gwinn, Vivian Enzenbacher, Esther Grow, Jean Laing, Margaret Riecks, and Pauline Karns of Nursing Service; William Gilmour of Dietary; Vivian Gilmour of Laundry.

From EAST PALO ALTO: Hazel Webber of Nursing Service; Jessie Martin of Hematology.

From LOS ALTOS: Flora Williams and Nell Parker of Nursing Service; Katherine Morales and Celestine Zangrando of Central Services.

From REDWOOD CITY: Pearl Searcy and Hazel Williams of Nursing Service; Kathryn Moore of Laundry; June Thompson of Labor and Delivery; Bessie Williams of Dietary; Gertrude Couch of Operating Rooms.

From SANTA CLARA: Helen Petrucci of Business Office; Delbert Hicks of Maintenance.

From SAN MATEO: George Barbieri of Operating Rooms.

From MOUNTAIN VIEW: Naomi Fell of Operating Rooms; Ona Williamson of Nursing Service; Margaret Hockensmith of Laundry; Dorothy Hirschberg of Dietary.

From SUNNYVALE: Genevieve Clark of Nursing Service.

From SAN JOSE: Frances Ingersoll of Medical Records.

From CUPERTINO: Loretta Harris of Nursing Service.

AOA HONORARY MEMBERSHIP AWARDED DR. WILLIAM W. GREULICH

Alpha Omega Alpha, the medical scholastic honors society, presented Dr. William W. Greulich, executive head of the Department of Anatomy of the Stanford University School of Medicine, with an honorary membership at its annual dinner last night (MAY 12).

Dr. Greulich is widely known for making the first survey of Japanese children who survived the atomic bombing of Hiroshima and Nagasaki, and then following their subsequent growth and development. His findings in the skeletal development of individuals of different races have set scientific standards in the field. He was science adviser to Dr. James B. Conant, U.S. High Commissioner for Germany between 1952 and '54, and was chairman of the Fulbright Commission between 1953 and '54.

The members of AOA initiated the award as a particular tribute to Dr. Greulich, a Ph.D. and not an M.D. eligible to regular membership, for his long and distinguished career as an anatomist and teacher. The topic of Dr. Greulich's address at the dinner was "Books and their Authors."

The AOA dinner also welcomed to its membership seven students of the class of '61, and three of the class of '62: William Abbott, John Bruner, David Hunt, Donald Johnson, Bernard Nelson, R. Cree Pillsbury and Donald Prolo of '61; Donald Doty, Laurence Kedes and Victor Lavis of '62.

Only those in the upper one-fifth of a Medical School class are eligible to membership in AOA, and only one-sixth of a graduating class may be elected to it. Of 52 medical students graduating from the Stanford School of Medicine this June, nine are in AOA, with John M. Simpson, Jr., serving as president of the Society.

HOSPITAL WEEK TOUR OF STANFORD MEDICAL CENTER PLANNED SUNDAY, MAY 14

Palo Alto-Stanford Hospital Center will celebrate national Hospital Week by holding an open house with a tour through Stanford Medical Center on Sunday, May 14, from 3 to 5 p.m., Administrator Oliver E. Deehan announced today.

Six areas in the Hospital Center and the Stanford University School of Medicine will be displayed to demonstrate the complex and diversified parts which make up a major medical center. Examples of diagnostic and therapeutic equipment, supporting services and teaching laboratories will be shown.

A special parking area will be reserved for visitors. This area is at the end of Edwards Building, the first building on the right as you drive toward the Center from Willow Road.

Volunteers from the Hospital Center Auxiliary and the Gray Ladies of the American Red Cross will be stationed along the tour route to assist visitors.

The tour will begin in the Hospital lobby. Stops will include Physical Medicine where physically handicapped patients are treated; the laboratories used by medical students when they are learning basic medical sciences; Cardiology, where diagnostic studies are made on patients with heart disease; the Pediatric playroom; Therapeutic X-ray where cancer patients are treated; and the Dietary Department.

FOREIGN SERVICE POST SET FOR STANFORD MEDICAL SCHOOL PROFESSOR

Dr. William W. Greulich, executive head of the Department of Anatomy at Stanford University School of Medicine, has been named senior scientific attache for the United States Embassy in London.

From 1952 to 1954 Dr. Greulich held a similar post when he was science advisor to Dr. James Bryant Conant, then U. S. High Commissioner for Germany.

He will be responsible for advising embassy officials on scientific issues, expediting exchange programs such as the Fulbright scholarships, visiting universities in Great Britain and attending scientific meetings as an official United States representative.

Dr. Greulich is now en route to Washington, D.C., where he will spend about two weeks before going to England late in July. He will be on sabbatical leave from Stanford while he is in London. Professor Donald J. Gray will be acting executive during his absence.

The Stanford executive is widely known for his studies of the growth and development of children. He has documented the retardation among Japanese youngsters who survived the atom bombs dropped on Hiroshima and Nagasaki.

He has also examined children to study differences in development among different races.

Dr. Greulich received degrees from Kenyon College and the University of Denver before winning his Ph.D. at Stanford in 1934. He has been on the Stanford faculty since 1944.

MEDICAL STUDENTS, INTERN RECEIVE AWARDS AT MEDICAL SCHOOL CONVOCATION

Nine outstanding students of the Stanford University School of Medicine and an intern in the Palo Alto-Stanford Hospital Center received awards at the convocation of the class of 1961 held at Stanford Medical Center Saturday (JUNE 17).

Dean Robert H. Alway presented the awards to the men, after which the faculty address was delivered by Dr. David A. Rytand, Arthur L. Bloomfield Professor of Medicine at Stanford.

Dr. Bloomfield, professor of medicine emeritus, then administered the Hippocratic Oath to the new physicians. Dr. Bloomfield served on the Stanford faculty from 1928 to 1954 and is one of the University's most distinguished physicians and revered teachers.

Student Donald J. Prolo received the Borden Undergraduate Research Award of $500, given him for "research during his undergraduate career deemed most meritorious." He was also one of the five top-ranking senior medical students receiving a Mosby Scholarship Book Award.

John Bruner, David Hunt, Donald Mason and Ronald Pillsbury were the other students to receive Mosby Scholarship Book Awards, each worth up to $30.

The Hopkins Award of $100 for the outstanding senior medical student in dermatology went to Stephen Bennett.

The Merck Manual Award, offered to each of two outstanding senior medical students, went to William Abbott and Ralph Gianelly.

Douglas Bowden, a second-year student, was given the Roche Award of an Omega wrist watch as an "outstanding student of medicine who has successfully completed the first two years of medical school."

- more -

Clayton Feldman, M.D., received the Julian Wolfsohn Award of $100 as the "intern at the Stanford University Hospital who, during the year, did the best work in neurology or internal medicine."

EDITORS: Students and their parents' names and addresses are listed below:

Donald Prolo, Mr. and Mrs. James R. Prolo, 1163 Crescent Dr., SAN JOSE.

John Bruner, Dr. A.M. Bruner, HOT SPRINGS, SOUTH DAKOTA, and Lois C. Bruner, 2909 E. Lester Dr., TUCSON, ARIZONA.

David Hunt, Mr. and Mrs. Arthur J. Hunt, 4237 Drakes Brand Rd., NASHVILLE, TENNESSEE.

Donald Mason, Mr. and Mrs. Milton D. Mason, 406 Warren St., MANKATO, MINN.

Ronald Pillsbury, Dr. and Mrs. S.G. Pillsbury, 4035 Country Club Dr., LONG BEACH.

Stephen Bennett, Prof. and Mrs. Merrill K. Bennett, 1103 Ramona St., PALO ALTO.

William Abbott, Mr. W.L. Abbott, 822 G St., ARCATA, and Mrs. Gene Walker, 330 Cherry St., SAN FRANCISCO.

Ralph Gianelly, Mr. and Mrs. Eugene G. Gianelly, 20 Bow St. Ct., STONEHAM, MASS.

Douglas Bowden, Prof. and Mrs. D.J. Bowden, 936 S. High St., BLOOMINGTON, IND.

Dr. Clayton Feldman, Mr. and Mrs. David Feldman, 2718 N. 58th St., MILWAUKEE, WIS.

#######

(Mailed June 20, 1961)

Note to editors: All the students except Douglas Bowden received their M.D. degrees at Stanford's commencement Sunday (JUNE 18).

COST CUTS SAVE COUNTY MONEY FOR STANFORD CLINICS PATIENTS

Charges to Santa Clara County for psychiatric patients treated in the Stanford Clinics under the Short-Doyle Act will be reduced 13 per cent per patient visit during the coming year.

The savings are a result of lower operating costs in the Clinics since a year ago. County charges will drop from this year's $7.29 per visit to $6.31 next year. The reduced costs will also result in lower charges to the patients themselves, since they pay fees which are supplemented by Short-Doyle funds.

The Santa Clara County Board of Supervisors Wednesday (JUNE 14) approved $54,000 in the budget of the County Health Department to cover expenses of the program. A contract between the Department and the Palo Alto-Stanford Hospital Center was signed in May, but was contingent upon Board allocation of the necessary funds.

The Short-Doyle Act provides matching funds for counties to provide psychiatric care for its residents. Patients are charged fees based upon family income. The state and county funds make up the difference between patient charges and actual clinic costs.

Patient charges are based on the Heller guide, a scale which offers a guide for charges depending upon several factors, including family income, expenses, and the number of persons in each family.

Average cost per visit in the psychiatry clinic last year was $12.82, but has been estimated to be 7.6 per cent less, or $11.84, for 1961-62. This lower cost will be reflected in reduced charges to the county during the fiscal year beginning this July 1.

TWO FACULTY APPOINTMENTS AND TWO NEW DEPARTMENTS ANNOUNCED

An internationally recognized tissue chemist and an outstanding anesthetist will join the faculty of the Stanford University School of Medicine on Sept. 1, Dean Robert H. Alway announced today.

The new appointees are Dr. David Glick, professor of pathology, and Dr. Vernon Thomas, associate professor of anesthesia. Dr. Glick is currently professor of physiological chemistry and director of the Histochemistry Laboratory at the University of Minnesota. Dr. Thomas is a former professor and chairman of the Division of Anesthesia at the University of Rochester, N.Y.

Dean Alway also announced the formation of two new departments in the medical school, Anesthesia and Dermatology. Until recently they were divisions of the Departments of Surgery and Medicine respectively.

Executive head of the Department of Anesthesia is Dr. John P. Bunker, who came to Stanford from Harvard last year as professor and head of the division.

The Department of Dermatology is headed by Dr. Eugene M. Farber, who has been professor and division chief from 1950 to the present. Dr. Farber is directing the department's extensive, multi-discipline investigation of psoriasis, the disfiguring skin disease which afflicts millions of Americans.

In the Department of Pathology Dr. Glick will organize and direct research activity in micro-histochemistry. Histochemistry is the study of chemical substances in body tissues, and is frequently conducted at the cellular level.

- more -

For many years Dr. Glick has contributed to the development of new techniques of chemical analysis using very small samples, such as microscopic fragments or single cells. These have become widely used and are important in helping identify the elements of tissue that are responsible for specific chemical processes.

He has held his current post as professor at the University of Minnesota since 1950. He is the author of 149 papers in professional journals and publications, and is editor of the journal Methods of Biochemical Analysis.

He received his B.S. from the University of Pittsburgh in 1929 and his Ph.D. in biochemistry there in 1932.

Dr. Thomas is considered an outstanding teacher and an expert in obstetrical anesthesia and the resuscitation of newborn infants. He has been in private practice in Rochester, N.Y., for the last two years.

From 1955 to 1959 he was chairman of the division of anesthesia at the University of Rochester. He was an associate professor from 1955 to 1958, and full professor the following year.

Dr. Thomas was born in the British Isles and holds three degrees from the University of Wales, a B.Sc., and M.B. and a B.Ch., the last two in medicine.

In 1957 he was elected a Fellow of the Faculty of Anaesthetists (cq) of the Royal College of Surgeons in recognition for his part in setting up exchange fellowships for young British anesthetists to come to the United States.

ACCIDENT LED TO LIFESAVING FOUNDATION--AND STANFORD NURSE'S CAREER

When Linda Collins steps up to receive her diploma from the School of Nursing at Stanford University's graduation ceremonies Sunday (JUNE 18) she will be wearing--as she always does--an unusual bracelet on her left wrist.

The story behind that bracelet is the story of an unlucky accident which set the lucky pattern of 22-year-old Linda's life today.

But for the accident which almost claimed her life eight years ago, Linda would not have entered nursing.

But for it, and the bracelet she wears, many who are alive today would have died or suffered unnecessarily.

But for it, and her success in championship golf, she would probably never have met the young doctor she will marry this fall.

The bright red letters on the bracelet read "MEDIC ALERT." There is also a picture of a staff with a snake entwined about it--the staff of Aesculapius, the symbol of medicine. On the back there is the message: "Allergic to Horse Serum, Aspirin, Sulfa Drugs."

It was Linda's allergy to horse serum which made her accident serious. When she was 14 a B-B gun lever snapped back and cut her finger. Her uncle, a physician, stitched up the wound but before giving her a routine anti-tetanus shot decided to give her a precautionary skin test.

His caution saved her life. Even the sample in the skin test was enough to send her into anaphylactic shock, a severe reaction which nearly killed her. A full dose surely would have been fatal.

--more--

It was during her recovery in the hospital that Linda changed her career goal from teaching to nursing. "I was so impressed with the nurses and their care of me," she says, "I wanted to be like them one day."

After her recovery, though, her surgeon father, Dr. Marion Collins of Turlock, Calif., was still worried. He feared that someone might unknowingly give Linda another anti-tetanus shot if she were ever in an accident.

At first he had her carry warning notes or wear them pinned to her clothes. But he knew these might get lost in an accident. When Linda came to Stanford, he suggested tattooing the warning on her leg or arm. Not surprisingly, she objected.

Putting their heads together they came up with the bracelet idea. But then Dr. Collins began to worry about the thousands of others like his daughter with allergies or unusual illnesses who might be in as much danger.

So in 1956 he founded the Medic-Alert Foundation to supply similar warning tags for all who need them. The foundation, with headquarters in Turlock, has grown until it is an international organization today.

Medicine is only one of two strong currents in Linda's life. The other is golf, which she started playing at the age of eight. As an undergraduate at Stanford she played in several tournaments. Last year she won the San Francisco City Women's Golf Championship.

Her championship led to the next big event of her life. When Stanford senior medical student John Maurer of Madison, Wis., read about it he decided he had to meet her, because she was interested in the two things he liked best: medicine and golf.

They met last April and played golf the same afternoon they were introduced. This September they will be married. John is now interning at the Hartford, Conn., Hospital, but will return to Stanford in July as a psychiatry resident.

Linda will go to work in the Palo Alto-Stanford Hospital Center this summer, but she expects to continue to mix golf with nursing. She'll be playing in the National Women's Intercollegiate Championship at Ann Arbor, Mich., later this month, and in the National Women's Open and National Women's Amateur during the summer.

#######

NOTE TO EDITORS: Linda's parents are Dr. and Mrs. Marion Collins, 1030 Sierra Drive, Turlock, California.

NEW HOUSE OFFICERS ON DUTY AT PALO ALTO-STANFORD HOSPITAL CENTER

Forty-three new house officers have just gone on duty at Palo Alto-Stanford Hospital Center, according to Administrator Oliver E. Deehan.

These young doctors are interns, residents, trainees and fellows who are receiving advanced medical training. They assist in the care of all teaching patients in the Hospital and in the Stanford Clinics. Some are also assigned to emergency, operating and delivery rooms, where they serve both teaching and private patients.

Fourteen states plus the District of Columbia and Canada produced the 43 newcomers; they trained for their M.D. degrees at 28 different medical schools in the United States and one in Canada.

New York and California contributed the greatest numbers, with California leading 13 to 10. Two of the new house officers are women.

With the new arrivals, the house staff for the year ending next July totals 183, including those doctors who will work part or all of the time at other hospitals associated with Stanford.

These other hospitals are Palo Alto Veterans Administration Hospital, San Mateo Community Hospital, Santa Clara County Hospital in San Jose, the Stanford Convalescent Home, and Presbyterian Hospital and Medical Center in San Francisco.

All of the young doctors care for patients but some are called trainees or fellows because they have received training grants or fellowships. The Hospital pays the salary of interns and residents who work there.

STANFORD HEART PATIENT TO RETURN TO BOLIVIA

Luisa Garron, 24, the girl from Potosi, Bolivia, whose brother brought her to this country four months ago for life-saving heart surgery, is flying home to Bolivia at 12:15 a.m. next Monday morning, July 24. Luisa's brother, Edmundo, 29, the former medical school student who borrowed $2,000 on a hospital orderly's pay (plus part-time pay teaching Spanish in two Redwood City public schools), to bring her to the Stanford Medical Center and pay for her hospitalization, is remaining in this area. He plans still to earn enough to start his own medical studies again. "If it takes until I am 50," he still says, "I shall be a doctor."

Dr. Norman Shumway, assistant professor of surgery at Stanford and head of the team which performed the operation, said on the eve of her departure: "Luisa has improved greatly since her operation and we expect her to continue to improve. She has an excellent chance to live a near-normal life, although she will never be as strong as a person with a normal heart. Without the operation, however, she would probably not have lived for more than a few years."

Chronology on Garron Story

December 1960	Edmundo Garron starts work as an orderly at the Palo Alto-Stanford Hospital Center in the Stanford Medical Center.
January 1961	Dr. Norman Shumway, assistant professor of surgery at Stanford University School of Medicine, offers to do open heart surgery on Luisa Garron without fee after being told about her condition by her brother, Edmundo. The same month Edmundo borrows $2,000 to bring Luisa to U.S.A. and cover cost of her hospitalization.
March 1961	Luisa arrives here. Her heart condition is more serious than at first suspected. It is mitral insufficiency, a congenital defect in which the ring around the mitral valve is overlarge so that the valve never entirely closes. Mortality rate for such corrective surgery is 33 percent.
April 4	Luisa has five-hour operation by Stanford 5-man heart surgery team, headed by Dr. Shumway. For 90 minutes her heart is stopped and she lives only by means of a heart-lung machine. Tucks are taken in overlarge valve ring. She remains on critical list for days.
April 16	Luisa leaves hospital to live with Mr. and Mrs. Wilbur Doxsee, 503 Arlington Rd., Redwood City. She begins to enjoy things other girls always take for granted but she never could have, such as trips to Carmel, San Francisco, Santa Cruz...
July 24	Luisa to fly home to Bolivia via United Airlines, Flight 848, 12:15 a.m. July 24, from San Francisco International Airport.

MEDICAL SCHOOL DEAN PARTICIPATES IN INTERNATIONAL SYMPOSIUM

Dean Robert H. Alway of the Stanford University School of Medicine is in Dundee, Scotland, this week, taking part in the International Symposium on Hospital and Medical School Design.

Dean Alway is one of only four Americans participating in the meeting. Most of the participants are from the United Kingdom. Sessions start Wednesday (JUNE 12) and run through Saturday.

The symposium is being held at Queen's College, the college of the University of St. Andrews (cq) which includes the University's medical school.

Dr. Alway is to speak at two sessions. During one he will outline the reasons why Stanford Medical Center was built as it was. He will cover the medical school's educational philosophy and the functional needs which had to be met to make the philosophy a working reality. When the Center opened in 1959 the school began a new five-year curriculum for medical students.

In the second session he will discuss the operation of the Max C. Fleischmann Laboratories of the Medical Sciences, the "home base" of medical students for the first three years they are at Stanford.

Professors come to the Fleischmann Laboratories to teach the courses which are given before students begin assisting in the care of patients. In most medical schools the reverse is true--the students must use different facilities for each course.

DIVISION OF CLINICAL SOCIAL WORK ESTABLISHED AT STANFORD MEDICAL SCHOOL

Dr. Daniel E. O'Keefe, until this summer chief of the Social Service Department of the 500-bed Clinical Center at the National Institutes of Health in Bethesda, Md., is chief of the new Division of Clinical Social Work in the Stanford University School of Medicine, Dean Robert H. Alway announced today.

The division is the first in the country with the aim of providing social work participation in all appropriate areas of the medical curriculum.

The new division will develop educational programs which stress the importance of social and emotional factors in the care of patients. Its work is expected to fit in with the emphasis on behavioral sciences in the new curriculum of the medical school.

Faculty and staff will also offer social service assistance to hospital and clinic patients at the Stanford Medical Center.

In addition to serving as chief of the division, Dr. O'Keefe holds the rank of associate professor. He began work late last month.

Dr. O'Keefe had held his post at N.I.H. since 1952. He was responsible for directing the medical and psychiatric social work in the Clinical Center, a 500-bed research hospital. His staff not only assisted patients but also collaborated in research carried on in the various medical disciplines and undertook independent research on the social and emotional aspects of long-term illness.

- more -

The new division chief is 46. He is married and has three children. He received his B.S. from the University of Dayton in 1936 and his M.S. in social work two years later from Catholic University in Washington, D.C. He received his Ph.D. from the University of Minnesota School of Social Work in 1955.

His professional experience includes service with the Veterans Administration, the Army Surgeon General and the U.S. Public Health Service.

He is a charter member of the National Association of Social Workers and was chairman of its Psychiatric Social Work Section from July, 1959, through June of this year.

CANCER RESEARCH CENTER ESTABLISHED AT STANFORD

A Clinical Radiotherapy Cancer Research Center will be established at the Stanford Medical Center this fall under a $943,412 grant from the National Cancer Institute, it was announced today.

Very few patients will be hospitalized under the Center's auspices until after Jan. 1, but eventually 15 beds will be occupied by research patients. Between 200 and 500 patients a year will be cared for under the program.

The new Center is one of eight cancer research units now being set up by the NCI in medical institutions across the country.

Investigators in several disciplines will join with the Stanford School of Medicine's Department of Radiology in the research involved. Major research areas will include:

1. Studies of the value of chemicals which enhance the effect of radiation for treatment of tumors.

2. Experiments with methods of altering the amount of oxygen reaching tissue for the purpose of changing radiation sensitivity.

3. Studies of tumor blood supply, which might lead to methods of selectively making some tumors more sensitive to X rays.

4. Exploration of methods of using radio-opaque agents to reveal early tumors of the lymphatic system, which is very susceptible to the spread of cancer from other sites.

5. Studies of skin ailments and gynecologic tumors which relate to the problems and techniques listed above.

- more -

The program director for the Cancer Research Center is Professor Henry S. Kaplan, executive of the Department of Radiology. Assistant Professor Malcolm A. Bagshaw, director of the radiotherapy division of the Department, will be deputy director.

New equipment needed in the Medical Center to support the research will include a second 6-million-electron-volt medical linear accelerator, to be installed near the present unit; a new X-ray lab for tumor diagnosis; and more facilities for the Isotope Laboratory.

The present medical accelerator is now being operated at full capacity for the treatment of patients by means of conventional supervoltage X rays. Built by Stanford physicists five years ago, it was the first of its kind in the United States and has become the prototype for similar installations in the United States and abroad.

In addition to supporting the research through August of 1962, the NCI has indicated that there will be funds allocated for six succeeding years. Allocations will be negotiated annually but are not to exceed stipulated ceilings of approximately $600,000 a year.

The grant will pay all of the patients' hospital costs and there will be no professional charges. Patients will be accepted for care only on referral from a physician and only after an evaluation by Stanford physicians as well.

When the program is ready to accept patients physicians in the area will be notified by the Department of Radiology.

For Release
Sunday, Sept. 24, 1961

National Aeronautics and Space Administration
Ames Research Center
Moffett Field, Calif.

Scientific devices to be used in answering one of the most exciting questions in modern biology, and in space science as well, are in preliminary stages of design at Stanford University School of Medicine under a $380,640 grant from the National Aeronautics and Space Administration.

The question is: Has life evolved in any way other than it did on earth?

The equipment is planned to be a part of a space probe which could land instruments on Mars and Venus in a series of planetary missions beginning 1966-67.

No specific devices have been completed yet, but preliminary studies under an earlier $37,605 NASA grant have laid the basis for reasonable objectives in the program. The new grant provides long-term support for the research through March, 1964.

The project is being directed by Dr. Joshua Lederberg, professor of genetics at Stanford and a co-winner of the 1958 Nobel Prize in Medicine. Associated with him is Dr. Elliott C. Levinthal, a research physicist.

In general, the scientists' approach is to try to design devices which could detect microscopic organisms or chemicals which are found in them. Specifically, these chemicals are nucleic acids, the very complex molecules which make up most of their structure.

"If life exists or has existed on a planet," Dr. Lederberg says, "evidence should be found in any drop of water, pinch of soil or gust of wind. With weight limitations in rocket payloads, we have little room to mount a trap for bear."

Findings related to microbes might help explain the origin of life on earth. Despite the great diversity of life forms, the central components of all of them are the same--nucleic acids and proteins.

"If we knew how specific proteins and nucleic acids first appeared on the earth," Dr. Lederberg said, "We would have most of what we need to understand the original development of life."

Great as the contributions to basic science could be, there are possible practical applications here on earth for equipment they might develop. A rapid monitor for micro-organisms might also serve as an alarm system for hospital operating rooms or for biological warfare defense.

Dr. Lederberg has already done considerable work on a microscope device which could be landed on a planet. It would put out a plastic tape which could pick up particles of matter and pull them before a microscope. A television camera would then transmit the microscope's picture back to earth.

The scientists are exploring these other possibilities too:

1. Concentration of living organisms by flotation methods which would separate them from heavier mineral materials.

2. Optical analysis of specimens to detect those most valuable for further study; this is particularly important because microbes are known to absorb certain parts of the spectrum of ultraviolet light.

3. Use of chemicals which have a specific effect on materials found in organisms; for instance, certain natural chemical catalysts called enzymes attack specific nucleic acids, so the acids' presence could be detected by this means.

4. Detection of the presence of enzymes in material, which would then indicate the presence of living or once-living organisms.

5. Artificial cultivation of microbes in the equipment, using a method similar to present ways of growing microbes in laboratory test tubes.

STANFORD TO TAKE PART IN NATIONWIDE STUDY OF HIGH BLOOD PRESSURE

Stanford University School of Medicine is one of eight institutions in the United States taking part in a new cooperative study of patients with high blood pressure, one of the leading causes of death in the United States.

Patients will be given exhaustive diagnostic tests to determine as nearly as possible the exact cause of the disease in each case. The cost of these diagnostic tests will be covered under the program, but surgical and medical treatment will not be paid for by the grant.

High blood pressure, either alone or with accompanying heart and circulatory ailments, accounted for almost 20 per cent of the deaths in the United States in 1959.

The new study is being financed at Stanford by a $19,350 grant from the National Heart Institute. Dr. Thomas A. Stamey, associate professor of surgery and head of the division of urology, is directing the investigation.

One purpose of the research program is to try to confirm growing evidence that hypertension, or high blood pressure, is caused by the kidney. Another aim is to find out which of seven newly developed tests is the most reliable in showing when the hypertension is caused by the kidney and whether it can be cured by surgical treatment.

Present indications are that an obstruction which reduces arterial blood flow to the kidney leads this organ to produce "renin," a chemical which sets in action a chain of events leading to a rise in the blood pressure.

- more -

Dr. Stamey, while at the Johns Hopkins Hospital in Baltimore, Md., developed a new test for identifying kidneys responsible for high blood pressure. This is one of the tests being evaluated at the eight participating universities.

Surgery is already effective in many cases which are clearly due to arterial obstruction. A partial block in the artery may result from infection, deposit of fatty material, an inborn defect or other conditions.

The Stanford investigators say that it is particularly important for hypertensive patients under 30, and for those in the 40-70 age bracket who have developed high blood pressure in the last year or two, to seek treatment.

In both situations it is almost certain that the kidney condition is to blame. In both cases the condition may be corrected by surgery with a cure rate of about 85 per cent.

NOTE TO EDITORS: This is background material for a press conference to be held at Foothill College in Los Altos on Wednesday, Sept. 6, at 2 p.m.

PARAPLEGIC, AFTER FIVE YEARS IN HOSPITALS, RETURNS TO COLLEGE

Russell Thorp, a paraplegic of 34, who has been in the Palo Alto-Stanford Hospital Center longer than any other patient--since December 1, 1959--is planning to start classes at Foothill Junior College on Wed., Sept. 6 at 1:00 p.m. A press conference will be held there with him at 2:00 p.m. on that day, in the office of the Mass Communications Division. This is in the 1-story brick building to the left of the Administration Building.

Mr. Thorp, who is from Wyoming, was an active young man who served as an intelligence officer in the Army and was athletically inclined before the accident that made him a paraplegic five years ago last June. He was supervising a lumbering operation in northern Idaho when a tree fell on him. Since that day, he has been in hospitals, hopelessly paralyzed from the waist down, undergoing numerous operations and in a rocking bed for much of the time. Late last December he lost one of his legs to an infection.

Through the five years in the hospital, Mr. Thorp has maintained one interest that dates back to a year at the University of Wyoming (he also attended Amherst College for a year): he studied and has continued to study the Russian language. This interest has attracted to him such people as Alexander Kerensky, once premier of pre-Soviet Russia, and many of the White Russian community of this area who gave him two Christmases last holiday season, both Western style on December 25, and Russian style on January 7.

After attending Foothill College for a year, Mr. Thorp plans to enter Stanford to complete his education.

He is also planning shortly to leave the hospital, to live in a large house in Palo Alto where he will board students as a means of livelihood. He also expects to learn to care entirely for himself.

If you are interested in sending someone to the press conference at Foothill College, you should telephone this office to confirm that Mr. Thorp will attend his first class as planned. An infection may postpone this for a short while.

Foothill College is on El Monte Avenue, Los Altos, 1½ miles south of Fremont.

NOTE TO EDITORS: For release to P.M. newspapers of November 2, 1961. The following story is timed for release following presentation of a report to the American Society of Tropical Medicine and Hygiene in Washington, D.C. Dr. Beal will be staying at the Willard Hotel during the meeting. A photograph of the isolator in use is available.

DISPOSABLE PLASTIC BALLOON CAN BE "OPERATING ROOM" IN TROPICS

WASHINGTON, D.C.--Balloons have gone from the toy store to the edge of the atmosphere, but here's a new location for one--the operating room.

In fact a balloon of transparent plastic can be the operating room for all practical purposes, according to a pair of investigators from the Stanford University School of Medicine.

Dr. Charles Beal and medical student Daniel P. Stites of Margate, New Jersey, reported today on the effectiveness of using sterilized disposable plastic bags to provide a sterile field for operations in the tropics. Dr. Beal spoke this morning during the 10th annual meeting of the American Society of Tropical Medicine and Hygiene.

Dr. Beal first became interested in problems of tropical surgery while he was a Baptist medical missionary in what was then the colony of the Ivory Coast from 1951 to 1958. The colony has since become the Republic of the Ivory Coast. Dr. Beal is now instructor in preventive medicine at Stanford.

During his stay in Africa he was the only surgeon serving a population of 700,000 people. He frequently had to worry not only about keeping germs out of wounds but moths and flies as well.

His solution is to attach a sterile plastic bag to the patient's skin with a "surgical adherant" or sterile glue. The surgeon then slips his arms through the sides of the inflated bag to do the operation.

- more -

A special tray of surgical instruments has been designed to go with the bag. It has a plastic cover which will stick to the bag. The cover and bag are then opened with a solvent so that the instruments are inside the bag's sterile area too.

The bag is called a "surgical wound isolator." It is kept inflated like a balloon by a small pump. The air coming in is filtered by sterilized cotton. Dr. Beal says that the air is thus kept almost entirely germ free.

Other research groups have developed plastic units with arm holes for completely germ-free surgery, but Dr. Beal says these are too expensive to replace after every operation. One of his isolators uses about 50 cents worth of plastic and fabrication costs are small.

The bags are cut so that four points project from them. These are then cut for the surgeons to get their hands inside. Eventually it may be possible simply to make large rolls of plastic tubing from which enough for each operation could be cut off.

Beal and Stites conducted bacteriological studies during 12 operations with the arrangement last summer at the Hospital Rosales, San Salvador, in the Central American country of El Salvador. They also studied eight "control" operations without the isolator. There were no infections after any of the 20 operations.

Dr. Beal says this was probably because antibiotics were used in all 20 cases. But he pointed out that "You can't use antibiotics forever because eventually resistant strains of the germs develop."

The new technique will be particularly valuable in developing countries where well built operating rooms with careful maintenance and cleaning are often not available, Dr. Beal believes. Its possible applications to modern hospital practice, to military surgery and disaster situations, and to veterinary surgery are yet to be explored.

NOTE TO EDITORS: A press conference will be held at Stanford Medical Center with three of the participants of the Conference on Obesity and Adolescence Friday, Oct. 20, 1961.

The press conference will be held in a conference room in the School of Nursing, Room M127. It will begin at 2 p.m.

Details on the conference itself are covered in the attached announcement from the American Medical Association.

Taking part in the press conference will be the following:

Dr. Edmund Volkart, professor of sociology at Stanford and director of the Stanford Program in Medicine and Behavioral Sciences. His topic Saturday will be "Sociological and Cultural Aspects of Weight Control." He said he plans to discuss the problem of "creeping obesity," or the tendency for people to gain weight because social influences encourage caloric intake and discourage exercise to use up the calories. (Dr. Volkart will talk at 11:15 Saturday morning and his remarks are for release to P.M. newspapers of Saturday.)

Dr. Hilde Bruch, clinical professor of psychiatry at Columbia University College of Physicians and Surgeons. Dr. Bruch is widely known as the author of the book Don't Be Afraid of Your Child--A Guide for Perplexed Parents. She will discuss "Psychological Problems of Overeating and Obesity" on Saturday. (Dr. Bruch will speak at the afternoon session Saturday and her remarks are for release to newspapers of Sunday.)

Dr. Luigi Luzzatti, associate professor of pediatrics and preventive medicine at Stanford. Dr. Luzzatti is on the panel for the afternoon session. He will discuss some of the biochemical problems related to obesity in order to balance the presentation as it will be balanced in the symposium itself. (Dr. Luzzatti's material will be for release to newspapers of Sunday.)

NEWS RELEASE from
THE AMERICAN MEDICAL ASSOCIATION
535 North Dearborn Street • • • Chicago 10, Illinois • • • Phone: WHitehall 4 - 1500

FOR IMMEDIATE RELEASE

CHICAGO--An exploration into the serious problem of obesity among teenagers will be the subject of a symposium sponsored by the American Medical Association's Council on Foods and Nutrition.

The one-day conference will be held at Stanford University, Stanford, Calif., Saturday, Oct. 21. Co-sponsors include the Department of Pediatrics of the Stanford School of Medicine, California State Department of Health, California Medical Association, Santa Clara and San Mateo County Medical Societies.

Conference moderator will be Dr. Norman Kretchmer, Stanford University School of Medicine. The dean of the School of Medicine at Stanford, Dr. Robert H. Alway, will deliver opening remarks.

The morning session will deal with fat metabolism and various aspects of weight control. Psychological aspects of overeating and obesity, evaluation of calorie needs, and a panel discussion of the obese adolescent, will conclude the program.

Participants include Drs. Harold Harper, University of California School of Medicine, San Francisco; William Parson, University of Virginia School of Medicine, Charlottesville; Edmund Volkart, Stanford University; Hilde Bruch, Columbia University College of Physi-

cians and Surgeons, New York; Dr. Josef Brozek, Lehigh University, Bethlehem, Pa.

In addition to Drs. Bruch and Volkart, panel participants are Drs. Harry Jennison, Stanford University School of Medicine; Leslie Corsa, Jr., California State Department of Public Health, Berkeley; Luigi Luzzatti, Stanford University School of Medicine.

Advance registration may be made with the Council on Foods and Nutrition, American Medical Association, 535 North Dearborn, Chicago 10, Illinois.

FOR RELEASE AFTER 3:30 P.M. (E.S.T.) FRIDAY, OCT. 20, 1961

NOTE TO EDITORS: The following story is timed for release following presentation of an invited lecture at the annual meeting of the American Heart Association in Miami Beach, Florida. Dr. Abrams will be available for interviews at the meeting. He will be staying at the Bal Moral Hotel. Still photographs of a typical X ray are available.

3-D X-RAY MOVIES USED TO DIAGNOSE HEART DEFECTS

MIAMI BEACH--Three dimensional X-ray movies of the heart offer the best method of detecting and exactly locating serious defects of the heart and the major blood vessels near it, a Stanford University radiologist said today (OCT. 20).

Dr. Herbert L. Abrams, associate professor of radiology at Stanford's School of Medicine and director of the Diagnostic Radiology Division, reported on 4½ years' experience with such 3-D movies during a lecture at the annual meeting of the American Heart Association.

The Stanford X-ray device for taking such movies is known as a biplane cineangiocardiographic unit. It is unique in its capacity to get simultaneous movies of the heart from the front and side, with ultrashort exposures (1/1000 second) at very low radiation doses to the patient. Since 1957 more than 250 patients have been tested with it.

Dr. Abrams said that one-dimensional movies are now an important tool in diagnosing congenital heart disease. But these may not show up certain kinds of defects.

He said that it is particularly important to be able to pick up small defects to know whether surgery is necessary or not.

- more -

In some cases, a heart murmur due to a small shunt may not need to be operated upon. Proper diagnosis may spare a patient unnecessary surgery or make it possible for him to lead a normal life which would have been impossible if he thought he had a serious heart condition. In other cases, surgery is essential and must be based on a correct diagnosis.

The 3-D unit's movies can then be shown side by side to give an accurate view of the heart in three dimensions.

Advantages of this technique are:

1. Valve defects or narrowing of blood vessels will show up clearly. In a single projection, there may be an overlap of parts of the picture which make diagnosis difficult or impossible.

2. Holes in the center wall of the heart or small connections between the blood vessels can be located exactly and their size determined. This way the surgeon knows exactly what he has to repair.

3. Simultaneous photography from front and side gives two pictures which can be compared against each other if the diagnosis is unclear. This is better than separate views taken at different times.

4. Only one injection of the "dye" which shows up on X ray need be used. This reduces the hazard to the patient.

Exposure from the Stanford device is small, only one-fifth of that in the so-called "G.I. series," a commonly done X-ray study of the stomach and intestines.

Recent improvements in the electronic image intensifiers produce a fluoroscopic image 3,000 times brighter than the fluoroscope in a doctor's office. The brightness and the use of high speed film makes low X-ray dosage possible.

The X rays are also pulsed for one-one thousandth of a second 50 times per second. Thus the full power is on only 5 per cent of the time the patient is under the camera.

The heart action becomes visible when the doctors run a plastic tube or catheter from a blood vessel in the arm or in the groin into the heart, and then inject a liquid which absorbs X rays.

FOR RELEASE TO AM PAPERS OF FRIDAY, OCTOBER 6, 1961

NOTE TO EDITORS: The following story is timed for release following presentation of a paper at the annual meeting of the American College of Surgeons in Chicago. Dr. Boyd will be at the meeting and will be available for interviews there. He will be staying at the Hilton Hotel.

COOLING TECHNIQUE MAY INCREASE TIME AVAILABLE FOR BRAIN SURGERY

CHICAGO--Stanford University surgeons have successfully demonstrated a new technique that should greatly increase the amount of time available for delicate operations in or near the brain which necessitate stopping the circulation to that vital organ.

In order to avoid damage to the brain, which can go without blood for only three or four minutes at normal body temperature, the surgeons circulated cold blood to a patient's head and lowered the brain temperature to about 68°F., or about 30 degrees below normal.

In the one successful operation so far circulation was stopped for 10 minutes. There are preliminary indications from experimental studies on animals, however, which suggest that the blood flow might possibly be halted for up to one hour without harming the patient.

The new technique was described yesterday at a meeting of the American College of Surgeons by Dr. Robert J. Boyd, a United States Public Health Service Research Fellow at Stanford University School of Medicine. Co-author of the paper is Dr. John E. Connolly, assistant professor of surgery at Stanford.

- more -

Surgeons now may cool a patient's whole body to lower the brain temperature. With this procedure it is not considered safe to stop brain blood flow for longer than 10 to 15 minutes. Should the new method prove safe to use for an hour, it would multiply by four the amount of time available for operations deep in the brain.

By locally cooling the brain while keeping the rest of the body near its normal temperature, the Stanford surgeons avoided certain disadvantages of whole body cooling. One disadvantage is frequent loss of the regular heart rhythm at temperatures below 86°F. A heart-lung machine may be used to bypass the heart during the operation, but this significantly reduces the patient's chances for survival.

At 68°F. the metabolism of the brain is slowed to a standstill. Its cells can then do without the oxygen, normally carried in the blood, for long periods of time.

Dr. Boyd and Dr. Connolly used a pump and cooling device fed by blood from the iliac artery in the groin. The pump then fed cooled blood to a carotid artery in the neck. This is one of the major vessels supplying blood to the brain.

The patient was a 54-year-old woman with a recurrent vascular tumor in the area of the right mastoid and middle ear. It was considered inoperable unless the head's blood supply could be cut off, because it would bleed profusely in surgery.

The ear, nose and throat surgeon who removed the tumor had said he might need 20 to 40 minutes for the operation, but found he could perform it in 10.

The Stanford doctors feel the technique will be valuable where a bloodless area is needed in order to operate upon blood vessels and tumors inside the brain. Otherwise, intensive bleeding makes it difficult if not impossible for the surgeon to successfully perform the operation.

NOTE TO EDITORS: The following story is for release on Friday, Dec. 1, 1961. It is timed for release following presentation of a report at the annual meeting of the Radiological Society of North America.

BIG DOSES OF X RAYS BENEFIT EARLY CASES OF HODGKIN'S DISEASE

CHICAGO--A Stanford University radiologist reported yesterday an experimental study had shown "strikingly improved results" in the treatment of early cases of Hodgkin's disease, a malignant condition previously considered virtually incurable, using high doses of radiation instead of the conventional low doses.

This is not the first time high doses have been used for the disease. But it is the first time better results have been demonstrated in two different programs of treatment carried out concurrently on groups of patients with the same degree of illness, according to Dr. Henry S. Kaplan.

Dr. Kaplan, professor and executive head of the Department of Radiology at Stanford University School of Medicine, reported on the study at the annual meeting of the Radiological Society of North America.

He cautioned that his study was not strictly an "experiment" because the patients were not chosen at random. The treatment each received depended upon the type preferred at that time by the doctor who saw him.

Twelve of the 15 receiving high doses are alive today, all but one without recurrence of the disease. Dr. Kaplan suggested that the longest survivors, who have lived from 6 to 10 years, "may in fact be cured." But he warned this will not be known for 20 years.

Eight of the nine given lower doses of radiation are no longer living.

- more -

The idea of using high radiation doses was first proposed 20 years ago by a Swiss radiologist, Rene Gilbert. It has not been accepted by more than a handful of radiologists.

Hodgkin's disease is a cancer-like illness which attacks the body's lymphatic system. The average patient has a 25 per cent chance of living five years after the ailment is discovered. The five-year life expectancy is doubled with early diagnosis. All the patients in the Stanford study had been diagnosed early.

The disease is considered in early stages when still confined to one or two adjacent regions of the body, such as the chest and neck. Only about 20 per cent of the cases are so diagnosed now. If unchecked the disease can involve all the organs in the body.

Dr. Kaplan stressed the importance of detecting the disease early if patients are to be helped. "If the diagnosis is made while the disease is still confined to a fairly small area, the physician may still be able to offer the patient with Hodgkin's disease a real chance for cure," he said.

"There has been a tendency toward defeatism on the part of many doctors because Hodgkin's has been considered incurable for so long."

Fifteen patients were treated with doses of from 2,000 to 4,000 roentgens of radiation, which is from five to ten times the usual dose. The lower exposure usually eases the condition temporarily but rarely keeps the patient alive and well as long as ten years.

The dose Dr. Kaplan considers best is from 3,500 to 4,000 roentgens, with the total spread out over three or four weeks. It must include not only the whole area involved by the disease but the next chain of lymph nodes in each direction. This is because the disease tends to spread from one chain of nodes to the next, and is often present in microscopic form in apparently uninvolved nodes adjacent to the obvious tumor.

- more -

Twelve of the 15 patients are still alive, three after from six to ten years following treatment. One woman died six years after treatment for extensive Hodgkin's disease in the chest, including the heart, but had no signs of the disease on autopsy.

Her death, which was caused by delayed effects of the radiation on her lungs, might have been avoided with the more powerful "supervoltage" X-ray machines which have since been perfected, including medical linear accelerators like the 6-million-electron-volt one at Stanford, and cobalt machines. These can expose patients to large doses without burning the skin and can be more sharply localized to the involved tissues deeper in the body.

"I believe it is highly desirable that such high-dose treatment be given with supervoltage radiation," Dr. Kaplan said.

The other nine living patients have gone from 24 to 55 months, all but one without recurrence of the disease. Two patients died of Hodgkin's, but only one of these got radiation over as wide an area as is treated by the present technique.

Nine other patients with similarly localized disease were treated with smaller doses and served as controls. Most received the generally accepted dose of 400 roentgens, though doses up to 1,000 roentgens were used. While this checked the disease temporarily, all suffered recurrences, usually in 8 to 12 months. All but one are now dead; the lone survivor later received the "radical" dose when he developed recurrence, and is now free of disease almost three years later.

"Our results show that high doses of radiation (from 3,500 to 4,000 roentgens) are better for treatment than the usual dose of 400 roentgens," Dr. Kaplan said. "Whether the patients are cured will not be known for 20 years. That this is a better way to treat them, though, is shown now."

Dr. Kaplan said that in the new Clinical Cancer Radiotherapy Research Center in the medical school the high dose technique will be tried on patients with later stages of the disease to see whether it can also arrest the condition even when it is more advanced.

For Immediate Release

STANFORD MEDICAL ALUMNI DAY

The annual "Big Game" Banquet for Stanford Medical School alumni and wives at the Sheraton-Palace Hotel in San Francisco will be a highlight of the "Medical Alumni Day" on Friday, November 24. Cocktails, dinner, and dancing to Jimmy Blass' orchestra will be held in the Rose Room beginning at 7:00 p.m.

The Alumni Day activities will commence at 8:30 a.m. at the Stanford Medical Center, Palo Alto, with open house tours of the hospital and laboratories. These will be followed at 9:30 a.m. by Grand Rounds in Medicine, Pediatrics, and Surgery, with Drs. Halsted R. Holman and Roy Cohn presiding.

Dr. Clifford B. Cherry of Los Angeles, president of the Stanford Medical Alumni Association, will conduct a general meeting of the Association from 12:00 to 12:30 p.m.

A luncheon at 1:00 p.m. in the Rose Room of Rickey's Studio Inn will have as specially honored guests the fifty-year members of the class of 1911 and the Senior students of the Stanford School of Medicine. More open house tours will conclude the afternoon program.

Reservations for the luncheon and the dinner dance may be made by contacting the Stanford Medical Alumni Association office, Stanford Medical Center, 300 Pasteur Drive, Palo Alto.

"STAPH" INFECTIONS IN HOSPITAL NURSERIES CURBED BY NEW TECHNIQUE

SAN FRANCISCO--Doctors at the Stanford University School of Medicine have devised a new technique which almost completely wiped out dangerous staphylococcus bacteria in the Palo Alto-Stanford Hospital nurseries for a period of 20 months.

"Staph" germs have caused epidemics and in some cases several deaths in hospital nurseries in the United States and abroad. They are the chief cause of infection in maternity units.

A key part of the technique involves washing all infants immediately after birth and daily thereafter with a solution known to reduce staph infections. The aim of this technique is to keep the ever-lurking staphylococcus germs from reaching the skin of the infants.

The method has been tried at two hospitals with spectacular results. At the Palo Alto-Stanford Hospital in Palo Alto, Calif., an extensive bacteriological study of 777 infants turned up only 10 with staph on their bodies, or 1.3 per cent of the patients.

None of these, nor any of the other 5,188 babies born during the 20-month study, developed any staph infections in the hospital.

The lowest infection rate reported before was about 1 per cent. It may range up to 70 per cent, and appears to vary with the frequency with which staph are found on infants.

- more -

The new technique was described today by Dr. Sumner J. Yaffe, assistant professor of pediatrics at Stanford. He spoke this morning at a meeting of the Western Society for Pediatric Research.

Co-author of the report is Dr. Harold J. Simon, assistant professor of medicine and medical microbiology at Stanford. A similar study was conducted by Dr. Louis Gluck, formerly at Stanford and now an assistant professor of pediatrics at Yale.

The same technique was used at Yale University School of Medicine after its development at Stanford. Before it was put into effect one study of 500 infants showed 51 per cent carrying staph potentially able to cause disease.

But in 965 infants studied after the program started, only 3.1 per cent carried the germs.

In the average American hospital probably 40 per cent of the newborn children have such staph on their bodies. The rate may range from a low of about 25 per cent all the way to 100 per cent.

The fact that infants have staph on them does not mean they are infected. Most do not get infections. But the presence of potentially disease-causing germs means that highly susceptible infants are more likely to become infected.

Staph may cause boils, breast abcesses (in both mothers and children), pneumonia and blood stream infections.

The material used for washing the infants was a 3 per cent solution containing hexachlorophane. Nurses and doctors wash their hands in the same solution before handling each child. They also use the customary procedures such as wearing sterile gowns and restricting access to nurseries.

- more -

During a routine survey the Stanford doctors found two nurses carrying the epidemic causing strains of staph (type 80/81). However, they were never able to find these strains on any of the babies. This is an indication of the effectiveness of the preventive program.

Whereas none of the babies became infected with staph while in the hospital, seven of the 5,965 developed minor infections after leaving. At most four of these might have started in the nurseries--and it is very doubtful that any came from the hospital.

There are also other germs which can spread infections rapidly through a nursery, and the scientists suggest that some other means should be found to control these, since hexachlorophane is not entirely effective against them.

NONTECHNICAL ABSTRACT OF A PAPER TO BE PRESENTED AT THE DENVER MEETING OF THE AAAS, 1961

FILE COPY

Subject: Biosocial Aspects of Disease

Author: Edmund H. Volkart, Ph.D., Professor of Sociology and Director, Stanford Program in Medicine and the Behavioral Sciences.

Address: Stanford University School of Medicine, Palo Alto, Calif.

Convention Address: Brown Palace Hotel, Denver.

Time: Friday, Dec. 29, first speaker in morning symposium which begins at 9 a.m.

Place: Stratton-Tabor Room, Brown Palace Hotel, Denver.

Program: Symposium on Sociology of Medicine: Problems and Prospects. Program of the American Sociological Association.

THE STORY ATTACHED IS FOR RELEASE TO P.M. NEWSPAPERS OF FRIDAY, DECEMBER 29, 1961

Stanford Medical Center
News Bureau Palo Alto, California

FOR RELEASE: P.M. newspapers, Dec. 29 TELEPHONE DA 1-5310-11

NOTE TO EDITORS: Release of the following story is timed to follow presentation of a paper at the annual meeting of the American Association for the Advancement of Science. It is for release to P.M. newspapers of Friday, Dec. 29, 1961.

SOCIETY HELPS DETERMINE WHICH DISEASES PEOPLE WILL GET

DENVER--The society you live in has a key role in determining what diseases you are most likely to come down with during your lifetime, a Stanford University sociologist said today (DEC. 29).

Speaking at a joint meeting of the American Association for the Advancement of Science and the American Sociological Association, Prof. Edmund Volkart said there were four ways society or the "social environment" can influence the occurrence of disease, and that each requires more systematic research:

1. By modifying the physical environment. In industrial societies, for instance, emphasis on technological change and efficiency instead of health may underly problems of air pollution and the increasing frequency of respiratory ailments.

2. By encouraging certain routine behavior. Cigarette smoking, for example, is considered by many physicians as injurious to health. Or a common diet may cause disease, as beriberi may result from a diet largely made up of polished rice, which does not provide the vital B-complex vitamin thiamine.

3. By producing new stresses and problems of adaptation. The process of adapting to rapid social change, or to the high pressures of multiple and demanding social roles, can influence the occurrence of disease. This may be reflected in higher death rates among men, particularly in the middle years of life. The multiple roles for men include job and family obligations, which are complicated by emphasis on ambition and success.

- more -

4. By inviting people to be sick. "In our society most illnesses, even minor ones, tend to provoke reactions of sympathy, protectiveness and release from obligations," Dr. Volkart said. "Under these circumstances, sickness has a certain attractiveness as an escape from stress."

Recent recognition of the impact of society on health by scientists in many fields has led to a paradox in contemporary medicine, Dr. Volkart continued. On the one hand, there has been tremendous growth in understanding of illness, following advances in basic medical sciences such as biochemistry and genetics. On the other hand, more social scientists than ever are entering medical areas as teachers, researchers and consultants.

Dr. Volkart is one of these medically oriented social scientists himself. He is a professor of sociology and also directs the Stanford Program in Medicine and the Behavioral Sciences for the University's School of Medicine. Studies such as the AAAS report, as well as others under the Stanford Program, are supported by the Russell Sage Foundation.

Dr. Volkart is a consultant to the National Institute of Mental Health. One of his special interests has been human behavior in time of illness, and the reasons why people do or do not seek medical care.

The increasing interest in the social side of medicine, he said, has grown out of the changing character of disease (ailments due to stress and degenerative effects are of major importance today), the recognition of the frequency of psychosomatic illness, and the results of epidemiological studies which have shown different frequencies of disease and death in different social groups.

Results such as these have led scientists to study the way people live to see what effect this may have on the varying frequency and types of disease.

PRICING SYSTEM AND FORMULARY REDUCE PATIENTS' DRUG BILLS

A unique pricing system for drugs, together with a plan for prescribing them by non-proprietary rather than trade name, is saving patients at the Palo Alto-Stanford Hospital Center substantial amounts on their drug bills, according to Hospital Pharmacist John Oliver.

On expensive drugs usually prescribed for long periods of time the savings may reduce costs to patients by 50 per cent or more. The savings are less on less expensive medications.

The pricing and prescription systems have been in effect since early 1961. Top quality drugs from major manufacturers are used as before.

As far as is known, the pricing method is used by no other hospital in the United States, although it has been recommended by professionals in the field for a long time.

Prescribing by non-proprietary name instead of trade name is known as a formulary system. It has been an accepted practice in university hospitals for many years, but is not often used in hospitals with private medical staffs. The first formulary, in fact, was established at New York Hospital in 1816 (cq).

More than 90% of the private physicians on the staff of the Palo Alto-Stanford Hospital Center are voluntarily using this method for prescriptions. It is also used by the faculty of the Stanford University School of Medicine.

The purpose of the formulary is to cover the spectrum of therapeutic needs without unnecessary duplication of drugs.

- more -

Drugs are chosen for hospital use by a special committee of physicians which selects them from monographs offered on subscription from the American Hospital Formulary Service.

It was necessary to establish the formulary before major savings could be gained, Oliver said. Once a single type of drug was selected, instead of several virtually identical ones with different trade names, it was possible to purchase larger lots at lower cost.

Since the fall the Hospital Center has put major drug items out to bid and further reduced what it must pay for them.

"And all that we save is passed on to the patients by our pricing system," Oliver said.

The Hospital Center charges a flat fee for filling a prescription, instead of adding a percentage markup to the wholesale cost. Fees range from $1 to $4.50, but the average is $1.75.

The fee is determined by the complexity of the process of filling the order and does not depend upon the purchase price to the pharmacy. Oliver says this is the fairest way of covering the pharmacy's operating expenses.

The usual method of charging a markup penalizes the patient who needs a costly drug. And it costs just as much to process a prescription whether the drug costs a penny a unit or a dollar a unit. Care and accuracy is just as important in either case, he said, since the medication is important for the patient's recovery.

As an example of the savings involved, Oliver said that a well known broad spectrum antibiotic cost $30.60 per 100 tablets before the new plan went into effect. On a bid recently received, the cost is now $15.45 per 100.

One of the corticosteroids formerly cost $15 per hundred. The price the hospital now pays is less than $3.

The Hospital Center administration feels that while the economics of drug purchasing and pricing is important, there is also another gain with the method used here. The system reduces the number of drugs which must be kept track of by personnel, and it is assumed that this reduces the likelihood of any mishaps in giving drugs to patients.

A year ago the pharmacy stocked 3,000 different items. Now there are fewer than 2,000.

FOR FURTHER INFORMATION CONTACT:

NOTE TO CITY EDITORS AND SCIENCE WRITERS:

Early this year the Palo Alto-Stanford Hospital Center put into effect a unique pricing system for drugs. This pricing method, together with the formulary system for prescribing drugs by non-proprietary rather than trade name, is saving patients substantial amounts on their drug bills.

The combined plans have been in effect long enough to demonstrate their value. The savings to patients may exceed 50 per cent over the previous prices for expensive medications prescribed for long periods. The savings are less on less costly items. As far as is known, no other hospital in the United States uses the pricing method, although the formulary system is used widely in university hospitals.

Knowing the public concern about drug prices we thought this story might interest your readers. We have scheduled a press conference about it for Wednesday afternoon, December 20, at 1 p.m. Sandwiches will be served at 12:30 for those who may not be able to get lunch because of the early hour in the afternoon.

Attending the press conference will be the Hospital Pharmacist, John Oliver, who set up the plans, and Dr. Windsor Cutting of Stanford, who was an advisor during the planning stages. Mr. Oliver will leave the Hospital Center Jan. 1 to take a new job as coordinating director of the American Society of Hospital Pharmacists. Dr. Cutting is former dean of Stanford University School of Medicine and now professor of experimental therapeutics. He is also on the committee of the U. S. Pharmacopoeia, the official compendium of drug standards, and the reference committee of the American Hospital Formulary Service, which issues monographs describing all new drugs available for therapeutic use.

Lunch and the press conference will be held in the Board Conference Room, room C200, Stanford Medical Center. I would appreciate knowing by Tuesday whether a reporter from your publication will want lunch so we can be sure to order enough sandwiches.

STANFORD PSYCHIATRY DEPARTMENT NAMES PSYCHOLOGIST TO FACULTY

Dr. Joseph H. Handlon, for the last four years a research psychologist at the National Institute of Mental Health in Bethesda, Maryland, has joined the faculty of the Stanford University School of Medicine, Dean Robert H. Alway announced today.

He is an associate professor of psychology in the Department of Psychiatry. He will conduct research and teach in the field of psychological stress and adaptive behavior.

Dr. Handlon is the author of eighteen articles in professional journals, the latest of which deals with experimental methods for studying emotional and adrenal hormone responses to stressful experience.

He is a former instructor in psychology at Princeton, and holds an A.B. degree from UCLA and a Ph.D. from the University of California at Berkeley.

NOTE TO EDITORS AND WRITERS: The story below may be of added interest because of President Kennedy's comments Dec. 5 that "We are under-exercised as a nation. We look instead of play, ride instead of walk. Our push-button existence deprives us of the minimum of physical activity essential for healthy living."

'CREEPING OBESITY' IS CATCHING UP WITH MANY AMERICANS

"Creeping obesity" seems to be catching up with Americans as they spend less time working and more time eating, drinking and playing, according to a Stanford University sociologist.

Prof. Edmund Volkart says that "many social and cultural forces of our time are both pushing and pulling more people into caloric intake while at the same time reducing energy output."

While these forces don't mean that any individual will gain too much weight, they do mean that more and more people will become overweight as our easy living goes on.

Dr. Volkart's comments are contained in a survey of scientific literature on the subject of obesity. He stressed that he was not discussing overweight caused by specific disease states such as metabolic defects, glandular imbalance or psychiatric compulsions. "These diseases are important but they do not seem to me to account for the growing tide of 'plumpness' or 'overweight' or even 'obesity,'" he says.

Dr. Volkart is professor of sociology and director of the Stanford Program in Medicine and the Behavioral Sciences for the University's School of Medicine. He is a consultant to the National Institute of Mental Health. One of his special interests has been human behavior in time of illness, and the reasons why people do or do not seek medical care.

- more -

"Many labor-saving devices have subtle, almost hidden consequences for weight control," Dr. Volkart says. On the farm, a man driving a tractor will burn up fewer than half the calories he would per hour if he were walking behind a horse-drawn plow. Furthermore, he'll get the work done much sooner.

Even office workers use less energy. A typist using an electric typewriter will expend 15 fewer calories an hour than the girl who has to type on a manual machine.

At the same time, fattening foods are consumed in greater amounts than they used to be. Dairy products, candy and soft drinks are no longer luxuries but are often eaten daily.

And "the cocktail party, with its associated edibles, has practically become a social institution in professional circles and among the upper and middle classes."

The tendency to eat and drink persists despite the popular interest in slenderness, evidenced by the fact that "Metrecal" has become "a household word" almost overnight, Dr. Volkart says.

Doctors should consider these social and cultural pressures in dealing with their patients, the sociologist believes. While the medical profession has stressed that being overweight is bad for health and may shorten life, the message has not really gotten through.

For many "overweight is a remote state, not clearly identified with disease, and to them the pleasures of eating and indolence are here and now."

JET PILOT'S PRESSURE SUIT AIDS CRIPPLED PATIENT'S TREATMENT

The Air Force has teamed up with rehabilitation experts at Stanford Medical Center in using a jet pilot's pressure suit to help a bedridden patient begin sitting up for the first time in almost four months.

The patient is Anthony Dalla-Costa, a 67-year-old retired Redwood City salesman who broke his neck in an auto accident last October. The accident damaged part of the nervous system which helps regulate his blood pressure.

As a result, if he is tilted more than 25 degrees from the horizontal the blood rushes to his feet, his blood pressure falls and he becomes unconscious. But with the suit pressing against his legs and abdomen he can be moved toward an upright position without such a severe drop in blood pressure.

The pilot's suit is on loan from Edwards Air Force Base and has already been used to tilt him to 40 degrees without a serious change in blood pressure. The doctors hope Mr. Dalla-Costa can soon be placed in a wheel chair two hours daily with the suit on.

Air Force cooperation in the rehabilitation project was secured after a friend of Dr. David C. Chambers, senior fellow in the Division of Rehabilitation Medicine, contacted Brig. Gen. Irving L. "Twig" Branch, commander of the base. Within five days two Air Force men, Major Ralph Richardson and Mst. Sgt. George Grasser, arrived at the Medical Center to assist in fitting the suit on the patient. Dr. Chambers and Dr. Daniel J. Feldman, chief of the Division, are supervising Mr. Dalla-Costa's care.

TWO PROMOTED, ONE APPOINTED BY STANFORD MEDICAL SCHOOL

Two long-time members of the faculty of Stanford University School of Medicine, Dr. Herbert L. Abrams and Dr. Joseph P. Kriss, will be promoted to full professors Sept. 1, Dean Robert H. Alway announced today.

In addition, Dr. Seymour Levine of the Institute of Psychiatry at Maudsley Hospital, London, England, will join the Department of Psychiatry faculty April 1 as associate professor of psychology, Dr. Alway said.

Dr. Abrams is a world authority in diagnostic radiology, and is particularly known for his work with X-ray motion pictures of the heart. Now an associate professor of radiology, he is acting head of the Department of Radiology this year while Dr. Henry S. Kaplan is on sabbatical leave.

Dr. Abrams joined the faculty as an instructor in 1951 after completing his residency at Stanford. He was graduated from Cornell University in 1941 and received his M.D. degree five years later at Long Island College of Medicine. He and his family live at 961 Peninsula Way, Menlo Park.

Dr. Kriss will become professor of medicine and radiology. Among his special fields are endocrinology, nuclear medicine and the use of radioactive isotopes in the treatment of cancer.

He has also made major contributions to the development of the new curriculum in the medical school. He first came to Stanford in 1948 as a teaching assistant. He is a 1939 graduate of Pennsylvania State College and earned his M.D. at Yale in 1943. He lives at 735 Mayfield Ave., Stanford.

Dr. Levine, a stimulating teacher and imaginative and productive scholar, is now a fellow at Maudsley Hospital. Before going to England he was an assistant professor at Ohio State University from 1956 to 1960.

Receiving his B.A. in 1948 from the University of Denver, he earned M.A. and Ph.D. degrees from New York University in 1951 and 1952.

FOR RELEASE: Immediate TELEPHONE DA 1-5310-11

STANFORD RECEIVES $117,500 GRANT FOR NEUROPHYSIOLOGY RESEARCH LABS

The United States Public Health Service has approved a $117,500 grant to Stanford University School of Medicine toward construction of new neurophysiology research laboratories at Stanford Medical Center, Dean Robert H. Alway announced today.

The grant covers only half the estimated cost of the construction and fixed equipment. It must be matched by an equal amount from private sources. Another $145,000 for movable equipment will come from research grants and private donations.

The laboratories will be used by three members of the faculty of the Neurology Division of the Department of Medicine to conduct basic investigations of the functioning of the nervous system.

The facilities will be located in the basement of the Medical School Building, in space left empty during original construction of the medical center. They will occupy 5,191 square feet. They are expected to be ready for occupancy by this summer.

The laboratories will be the principal research facilities of the Division. Faculty members using the laboratories will be:

Dr. Frank Morrell, professor of medicine and head of the Division, for investigations relating to epilepsy and neurological mechanisms in learning.

Dr. Kao Liang Chow, associate professor of neurology, for further studies of brain function.

Dr. Anthony Iannone, assistant professor of neurology, for studies of the blood flow in the brain. Dr. Iannone's research is directly related to such conditions as the common "stroke."

Stanford Medical Center
News Bureau Palo Alto, California

FOR RELEASE: Sunday, Jan. 21, 1962 TELEPHONE DA 1-5310-11

NOTE TO EDITORS: The following story is timed for release following presentation of a paper before a Regional Research Workshop of the American Psychiatric Association, meeting at the University of Southern California School of Medicine.

IMPROVEMENTS CALLED FOR IN PSYCHIATRIC HOSPITAL CARE

LOS ANGELES--Major improvements in training programs for psychiatrists and in hospitalization procedures are needed if mental hospitals are to do a really sound job of caring for their patients, a Stanford University psychiatrist said yesterday (JAN. 20).

He said that young psychiatrists should get their earliest experience with the healthier patients instead of the sickest, as they now do. And he called for hospitals to treat patients more as patients than as "suspects" or "criminals."

The criticisms were contained in a talk by Dr. Seymour Kolko, assistant professor of psychiatry at Stanford University School of Medicine, during a regional workshop of the American Psychiatric Association.

"It is my contention that much in our day-to-day treatment regimes for the acutely psychotic person tends to prolong his illness or make it more severe," Dr. Kolko said.

He leveled his most serious charges at the training programs for men and women going into the field. These "still bear the format imposed on them at least 25 years ago." He urged the sequence of training be completely reversed.

A trainee should start with patients similar to those he saw in medical school and as an intern, then progress to more seriously ill ones.

- more -

Now, he said, "the most disturbed (and perhaps most disturbing) people are placed in the hands of those least trained, working in the poorest settings and receiving the fewest rewards in terms of status or salary." And as the young doctor gains experience he begins to care for patients who are less disturbed.

Doctors who take responsibility for these seriously ill patients may not be able to control their own feelings of doubt and insecurity, either, because they are so new to their profession. This is bound to affect patients.

"Turning our current residency programs around might not only serve to allow the beginning psychiatrist a chance to gain a better command of the information about the many causes of human behavior. It would also give him the time to gain the needed insight into his own reactions before dealing with the problems of others."

Looking at the setting for treatment, Dr. Kolko contrasted the institutional hospital atmosphere with the pleasant surroundings of a psychiatrist's office where the presumably less seriously ill patient receives his care.

Furthermore, hospitalized patients are often deprived of personal belongings that help them maintain their sense of identity. Admitting procedures are more like "interrogation of the suspect" than friendly seeking out of needed information.

Hospital personnel are often as "frightened and concerned" as the patients themselves. And they probably have hidden guilt feelings too, growing out of the still current idea that the hospital is a "bad" place rather than a place where the patient's ego can be restored.

CONTROL OF THE MIND SYMPOSIUM TO BE SHOWN ON TV AT STANFORD

The University of California Medical Center's international symposium on "Man and Civilization: Control of the Mind" will be shown live on closed circuit television in Stanford's Memorial Auditorium Jan. 26-29, it was announced today.

An 8-foot by 10-foot viewing screen will be installed especially for the symposium.

Five nations are represented on the distinguished faculty, which will be dealing principally with the problems of conformity and creativity.

The faculty includes specialists in the biological and social sciences, the humanities and creative arts. Discussions will emphasize innate individual potentialities, and the forces that encourage or restrict their development and expression.

Among the faculty members are William H. Whyte, Jr., author of "The Organization Man"; the internationally renowned Hungarian-born violinist Joseph Szigeti; Flavio deR. Carvalho, Brazilian architect, writer and painter, and one of the principal architects of Brasilia, his country's new capital.

C.H. Waddington of the Institute of Animal Genetics, Edinburgh, distinguished British biologist; Dr. Gardner Murphy, research director of the Menninger Foundation; Dr. Hadley Cantril, board chairman of the Institute for International Social Research; and Dr. Henry K. Beecher, Henry Dorr Professor of Research in Anesthesia, Harvard Medical School.

- more -

Sessions on Friday afternoon, Jan. 26, and Saturday morning, Jan. 27, will be of particular interest to professionals in the health and medical fields. They will cover the effects of drugs on mood and mental function.

General sessions will run from Saturday afternoon through Monday morning. Topics will be as follows:

Saturday afternoon, "Individual Potentialities"; Sunday morning and afternoon, Jan. 28, "Conformity and Diversity"; Monday morning, Jan. 29, "Creative Expression."

Tickets for the entire symposium will be available at the Stanford Memorial Hall box office beginning Jan. 22. Prices are $1 for university, college and high school students with valid student body cards, $5 for Stanford faculty, and $10 for all others. One-day tickets will be available, for all but students, at $2.50 each for Stanford faculty, and $3.50 for all others.

Programs may be obtained in person at the box office or by mail from the News Bureau, Stanford Medical Center, Palo Alto.

The television presentation is an experiment in the use of closed circuit transmission between the University of California and Stanford, according to Robert J. Wert, Stanford Vice Provost. If there is a good response, he said, similar events in the Bay Area may also be shown in this way.

This is the second UC symposium on "Control of the Mind." The first was held a year ago. The program committee for the present conference said the first generated such interest that a further examination of the many factors that influence human thought was planned.

The program is presented by the University of California School of Medicine and Continuing Education in Medicine and Health Sciences. Both symposiums have been supported by grants from the Schering Corporation and the Schering Foundation, Bloomfield, N.J.

###

(Mailed Jan. 15, 1962)

We are pleased to announce that the international symposium "Man and Civilization: Control of the Mind" will be shown on closed circuit television in Memorial Auditorium Jan. 26-29. The symposium sessions will be broadcast live from the University of California Medical Center.

We think this is a significant event. It provides an opportunity for faculty and students to listen in on the important discussions on conformity and creativity by the distinguished participants. Furthermore, it is a practical demonstration of the hoped for interplay between Stanford and the University of California. We sincerely hope it is only the first of many events to be transmitted to the campus from throughout the Bay Area.

We urge you to call the program to the attention of your fellows on the faculty, and to have as many of your students attend as is possible.

ROBERT J. WERT ROBERT H. ALWAY I. JAMES QUILLEN ROBERT R. SEARS

MAN AND CIVILIZATION: CONTROL OF THE MIND

Friday, Jan. 26 1:30 to 5 p.m. "Clinical Implication of Mood" Vincent Nowlis, Professor of Psychology, Rochester; Keith F. Killam, Associate Professor of Pharmacology, Stanford; Henry K. Beecher, Professor of Research in Anesthesia, Harvard.

Saturday, Jan. 27 9 to 12 a.m. "The Evaluation of Drug Action" Leo E. Hollister, Veterans Administration Hospital, Palo Alto, Calif.; Peter B. Dews, Associate Professor of Pharmacology, Harvard; Harris Isbell, Addiction Research Center, Lexington, Ky.

Saturday, Jan. 27 1:30 to 5 p.m. "Individual Potentialities" Benjamin Pasamanick, Columbus Psychiatric Institute, Columbus, O.; Gardner Murphy, Menninger Foundation, Topeka, Kansas; S. Rains Wallace, Life Insurance Agency Management Association, Hartford, Conn.

Saturday, Jan. 28 9 a.m. to 12:15 p.m. "Conformity and Diversity" Hadley Cantril, Institute for International Social Research, Princeton, N.J.; Rollo R. May, William Alanson White Institute, New York; Richard S. Crutchfield, Institute of Personality Assesment and Research, University of California, Berkeley.

Sunday Jan. 28 1:30 to 5:30 p.m. "Conformity and Diversity" Gilberto de Mello Freyre, North East Brazil Social and Educational Research Center, Brazil; C.H. Waddington, Institute of Animal Genetics, Edinburgh, Scotland; Maurice Mitchell, Encyclopedia Britannica Films, Wilmette, Ill.; Carl R. Rogers, Departments of Psychology and Psychiatry, Wisconsin.

Monday Jan. 29 9 a.m. to 12:15 p.m. "Creative Expression" Joseph Szigeti, violinist, Geneva, Switzerland; Flavio deR. Carvalho, writer, architect, painter, Sao Paulo, Brazil; William H. Whyte, Jr., author, New York.

TICKETS WILL BE AVAILABLE AT MEMORIAL HALL BOX OFFICE JAN. 22. Prices: For the entire symposium--$1 for students; $5 for Stanford faculty; $10 for all others. For single sessions--$1.25 for Stanford faculty; $2.50 for all others. Students must show student body card.

TWO NAMED TO PALO ALTO-STANFORD HOSPITAL CENTER BOARD BY STANFORD

Stanford University has appointed James E. O'Brien of Palo Alto and Mrs. Edward H. Heller of Atherton to the Palo Alto-Stanford Hospital Center Board of Directors, Stanford President Wallace Sterling announced today.

The appointments bring the newly enlarged board to its full complement of 12 members. Each of the Hospital Center's owners, Stanford and the City of Palo Alto, names six directors. The board's size was increased from 8 to 12 last year to spread the growing work load among more members.

O'Brien is a member of the law firm of Pillsbury, Madison and Sutro in San Francisco. He belongs to the California and American Bar Associations. He is also on the board of directors of W.P. Fuller & Co., San Francisco.

He received his B.A. degree from the University of California in 1932 and a J.D. three years later. O'Brien is married and lives at 1530 Waverley St., Palo Alto. His term will expire in 1964.

Mrs. Heller is the first woman to serve on the hospital board. Her appointment will run until 1963. She is a Mills College graduate and also holds an honorary doctor of laws degree from her alma mater.

Active in national Democratic Party affairs and on the boards of many educational institutions and health foundations, she has been a director of the Children's Health Council in Palo Alto and on the board of the Mental Research Institute of the Palo Alto Medical Research Foundation.

Last month Mrs. Heller was made a regent of the University of California to complete the term of her husband, who died on Dec. 18. Her home is at 99 Faxon Road, Atherton. She is the mother of two sons and a daughter.

STANFORD VETERINARIAN TO AID PANEL ON ANIMAL CARE

Dr. Orland A. Soave of the Stanford University School of Medicine is one of six specialists in the care of laboratory animals who are setting up professional standards for laboratory animal care and facilities in the United States under a contract with the National Institutes of Health.

As director of the medical school's animal facilities, Dr. Soave is responsible for supervising the care of 100,000 animals used for teaching and research. He is also assistant professor of preventive medicine at Stanford, and holds a degree in veterinary medicine.

Professional standards in the field are being established by the Animal Care Panel, an organization devoted to collecting and disseminating knowledge on laboratory animal care and management.

The committee of which Dr. Soave is a member will prepare a standards brochure to be published later this year.

Dr. Melvin M. Rabstein, president of the Animal Care Panel, said that the recent growth in research has led to the use of ever larger numbers of animals for scientific experiments.

The scientific community wants to be sure that professionally qualified personnel supervise animal facilities, that all people working in the facilities are properly trained, and that proper housing is provided for all the animals, Dr. Rabstein said.

Other members of the committee are Dr. Bennett J. Cohen of the University of California at Los Angeles; Dr. W.T.S. Thorp of the University of Minnesota; Dr. Thomas Clarkson, Bowman Gray School of Medicine; Dr. Bernard F. Trum, Harvard Medical School; and Dr. Robert J. Flynn, Argonne National Laboratory.

STANFORD PROFESSOR RECEIVES $30,000 LEDERLE AWARD

Dr. Gerald M. Reaven, assistant professor of medicine at Stanford University School of Medicine, has received a three-year, $30,000 Medical Faculty Award from the Lederle Laboratories, a division of American Cyanamid Co.

The Lederle awards are given to encourage and develop "the highest type of teachers and investigators to augment the regular full-time faculties of medical schools." The funds are awarded to the schools to attract younger people "of demonstrated capacities...to continue in a lifetime career of teaching, scholarship and research."

The awards subsidize salaries for young faculty members. The Lederle Laboratories provide the awards because they believe it important for private sources as well as government to support medical education.

Dr. Reaven's current work in the Metabolic Research Unit is investigating how an amino acid, leucine, lowers blood sugar concentration--a unique amino-acid effect.

At the University of Chicago Dr. Reaven took a B.A. (with honors) in 1947, and an M.D. in 1953. He was a U.S. Public Health Service Research Fellow in medicine at Stanford in 1959, and in 1960 became an instructor in the Medical School. He was made assistant professor last year.

NOTICE TO EDITORS AND SCIENCE WRITERS:

Why are more women than ever getting bald? Why are California's lepers now being treated at home and not in isolated institutions?

How can a skilled specialist detect signs of certain cancers, or liver, eye and thyroid conditions, just by a careful examination of a patient's skin?

These are some of the questions which will be answered at a conference on "The Skin and Internal Disorders" at Stanford this weekend (Saturday through Monday).

The conference is for physicians. It is being planned by Dr. Eugene M. Farber, head of the Department of Dermatology at Stanford University School of Medicine, and Clinical Assistant Professor George T. Wilson.

Participants in the conference will include Stanford faculty members as well as some of the leading dermatologists from medical centers across the country. Speakers include heads of departments at Harvard, Minnesota, Southern California and Oregon medical schools, the Mayo Clinic and the National Cancer Institute.

News conferences have been scheduled Saturday and Monday mornings at 10. They will be held in Room 102 of the Physics Lecture Hall, adjacent to the physics auditorium where the medical sessions will be held.

On Saturday news conferences have been scheduled with:

Dr. Paul Fasal, Stanford, "Leprosy on the West Coast"
Dr. Eugene Van Scott, National Cancer Institute, "Hair Fall" (Baldness)
Dr. Cecil J. Watson, Minnesota, "The Skin and Its Clues to Liver Malfunction"

On Monday these speakers will summarize some of the latest knowledge concerning the clues close examination of the skin can offer about internal ailments: Dr. Louis A. Brunsting, Mayo Clinic; Dr. Francis W. Lynch, Minnesota; and Dr. Thomas B. Fitzpatrick, Harvard.

FOR FURTHER INFORMATION CONTACT: Ann Walker (DA 1-5310)

NOTE TO EDITORS AND SCIENCE WRITERS:

Less than two weeks ago we sent you an announcement about a news conference with Anthony Dalla-Costa, the patient who wears a jet pilot's pressure suit to overcome his low blood pressure problem. The conference had to be called off because Dalla-Costa was suffering from painful shoulder muscle spasms.

The patient is now feeling much better, and the news conference has been rescheduled for 1:30 p.m., Wednesday, March 14. Background information follows:

* * * * *

Dalla-Costa can now sit up in a wheel chair and feed himself with a spoon. In late January, however, before the Air Force first fitted him with the pressure suit, he could not be tilted more than 25 degrees from the horizontal without blacking out. Because of an injury in an automobile accident almost four months before, the blood would rush to his feet when he was raised up.

Although his legs and arms are still paralyzed, Dalla-Costa has progressed so well he can sit upright in his wheel chair. He can also feed himself, using a special sling which supports his arm and lets him move his hand with his shoulder muscles.

Photographers and reporters will be able to see Dalla-Costa's suit pumped up with a bicycle pump, watch him lifted out of bed with a hoist, and see how well he can feed himself. Dalla-Costa will also be glad to answer questions from reporters.

One or both of the two doctors who have cared for the patient, Dr. David C. Chambers and Dr. Daniel Feldman of the Division of Rehabilitation Medicine at Stanford Medical Center, will also be on hand to discuss the case.

The news conference will be in Dalla-Costa's room, East 2A 212. If your reporter and/or photographer will come to the information desk in the main lobby of the hospital, the information clerk will direct them to the room.

Samuel Moffat (DA 1-5310)

FOR RELEASE SUNDAY, MARCH 11, 1962

NOTE TO EDITORS: The release date for this announcement was set by the Kennedy Foundation. The Foundation is distributing a similar release in the East. The Foundation is also holding a news conference in Madison, Wis., at 10 a.m. Saturday (CST). Mr. and Mrs. Shriver and Dr. Lederberg will be available for questions and photographs at the conference.

STANFORD MEDICAL SCHOOL RECEIVES $1,100,000 FROM KENNEDY FOUNDATION

One million one hundred thousand dollars was given to the Stanford University School of Medicine today by the Joseph P. Kennedy, Jr. Memorial Foundation.

One million dollars will be used to build a new research center for studies related to mental retardation. The remainder will be used over a four-year period to stimulate new educational and research projects in the field of mental retardation.

The award was announced today by Mr. and Mrs. Robert Sargent Shriver, Jr. following a meeting in Madison, Wis., of President John F. Kennedy's Panel on Mental Retardation. Mrs. Shriver is the sister of President Kennedy and a consultant to the Panel. Shriver is head of the Peace Corps. The Shrivers jointly administer the Kennedy Foundation.

Upon hearing of the grant, a distinguished Stanford alumnus, former President Herbert Hoover, said, "The Kennedy Foundation gift of $1,100,000 to Stanford University for research in mental retardation renders possible a magnificent contribution to the welfare of millions of our people--and to children especially.

- more -

"I am grateful that my alma mater should be chosen for this task," Hoover continued. "I am confident that untold benefits to human welfare will result from this most generous gift."

The new facilities will be known as the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine. They are dedicated to an attack on the problem of mental retardation on a broad front of scientific and medical research.

Dr. Joshua Lederberg, a 1958 winner of the Nobel Prize and head of the Department of Genetics at Stanford, will coordinate the research and educational activities of the Laboratories. Many disciplines will be represented in the research program, including biochemistry and genetics, as well as pediatrics, obstetrics, neurology and psychiatry.

Dr. Lederberg is a member of the President's Panel on Mental Retardation, which is surveying existing efforts and new approaches to progress in the field.

In announcing the gift, Shriver said, "Mental retardation is one of the most pressing medical and social problems in the United States today. Three per cent of the American population is afflicted by mental retardation. It affects 20 times as many people as tuberculosis and 600 times as many as polio.

"By establishing research units such as the one at Stanford we hope to accelerate investigations by outstanding scientists across the nation with the aim of discovering and eventually eliminating the causes of mental retardation."

The Kennedy Laboratories will be part of a new Clinical Sciences Building at Stanford Medical Center in Palo Alto, Calif. The building is expected to be ready for occupancy in 1964.

The building is being financed as part of Stanford University's current 100-million-dollar PACE Program, a three-year campaign to achieve greater excellence in higher education. The Kennedy Foundation grant is the sixth gift of one million dollars or more received so far in the drive, which is more than one-third of the way to the goal.

- more -

Under a matching grant from the Ford Foundation, the gift for the Kennedy Laboratories will bring in an additional $1 for every $3 received, or a total of $333,333 from the Ford Foundation. The initials PACE stand for "A $100 Million Plan of Action for a Challenging Era."

Research in the Kennedy Laboratories will cover broad, basic areas. "Mental retardation is one of the most compelling challenges to the humanitarian and social instincts of Medicine," Dr. Lederberg said. "It is also one of the most provocative challenges to investigative insight and experimentation across a broad frontier of scientific studies.

"It concerns the development of the most complex of biological functions, the most highly evolved organ of the body--the intelligent human brain."

Dr. Lederberg cautioned against limiting investigations to areas most obviously related to the critical disease situation. "Some of the most outstanding advances in our comprehension of the problems involved in mental retardation have come from entirely unrelated fields," he said.

Specifically, he cited medical knowledge about mongolism, which is now known to be caused by improper separation of chromosomes in the development of the egg before it is fertilized.

"Our understanding of this disease stems directly from the most general investigations of human chromosomes. These studies in turn grew out of earlier investigations of chromosome variations in the formation of species and varieties in domestic plants."

Some general research projects which have already been outlined for the Kennedy Laboratories include the following:

1. Characterization of the proteins which are produced in the brain in connection with its development and with the learning process. More basic information is needed here before an understanding of the chemical relationship of these proteins to disease and intellectual function can be gained.

2. Studies aimed at preventing premature births and at providing better care for premature infants. Up to half of all babies weighing less than 3.3 pounds, for instance, have some brain damage.

3. Detailed studies of the central nervous system, of chemical processes related to disease states, and of the effects of drugs on the developing infant.

The Kennedy Laboratories will provide space specifically for the genetics, pediatrics and obstetrics departments; in addition, scientists and physicians from several other departments are expected to take part in the research program, adding to its interdisciplinary flavor.

Dr. Lederberg will serve as chairman of a coordinating committee on mental retardation research. Other members will be the following professors: Dr. Norman Kretchmer, pediatrics; Dr. Arthur Kornberg, biochemistry; Dr. Frank Morrell, neurology; Dr. Robert H. Alway, pediatrics and dean of the medical school; Dr. David A. Hamburg, psychiatry; and Dr. Charles McLennan, obstetrics and gynecology.

- more -

In addition to providing stimulation and leadership in research, the committee will be responsible for reviewing and evaluating such research, for initiating and approving new projects, for recruiting new personnel, and for developing training programs and curricula for graduate and postgraduate studies in areas related to mental retardation, especially in its fundamental molecular aspects.

The Kennedy Foundation was established 16 years ago by Joseph P. Kennedy, former ambassador to Great Britain and father of President Kennedy. It is a memorial to Lt. Joseph P. Kennedy, Jr., who was killed in action in World War II while on a secret, volunteer mission over the English Channel.

Lieutenant Kennedy's abiding affection for children has inspired the Foundation to donate more than $16,500,000 thus far to institutions and research programs related to children's diseases, particularly mental retardation.

Notable among the institutions established in whole or in part by the Kennedy Foundation are the Joseph P. Kennedy, Jr. Memorial Hospital in Brighton, Massachusetts; Joseph P. Kennedy, Jr. Community Center in the Harlem District of New York; the Joseph P. Kennedy, Jr. School for Exceptional Children, Palos Park, Ill.; the Joseph P. Kennedy, Jr. Clinics in Washington, D.C.; the Joseph P. Kennedy, Jr. Child Study Center in New York City; and the Child Study Center adjoining St. John's Hospital in Santa Monica, Calif.

Mrs. Shriver, vice-president of the Foundation, was graduated from Stanford in 1944 with a degree in social sciences.

President Kennedy, honorary chairman of the Foundation's board, is a former Stanford student. He attended the University in 1940 for a time, auditing courses in business economics and political science. He left to join the Navy, in which he served throughout World War II.

NONTECHNICAL ABSTRACT OF PAPER TO BE PRESENTED AT THE ATLANTIC CITY MEETING OF THE FEDERATION OF AMERICAN SOCIETIES FOR EXPERIMENTAL BIOLOGY, 1962

Subject: "Caloric cost and fluid balance in a simulated arctic survival situation."
Authors: Terence A. Rogers, Ph.D. and James A. Setliff, B.A.
Address: Department of Physiology, Stanford University, Stanford, California.
Time: 11:30 a.m., April 16, 1962.
Place: Surf Room, Ambassador Hotel.
Program: Cold Adaptation (Physiology).
Convention address: Ambassador Hotel.

RELEASE TIME: P.M.'s, April 16, 1962

This experiment was the first of a series designed to yield quantitative information about the impact of cold and starvation on an ~~airman~~ who is forced to survive in the arctic. The results indicate that the greatest threat to survival is the danger of dehydration even though there is adequate water available (in the form of melted snow). This makes a man weak, more susceptible to cold and more likely to faint. He is particularly susceptible to frostbite, since blood volume is lowered and the circulatory system compensates for this by constricting the blood vessels. This sharply reduces the amount of blood reaching the hands and feet. The causes of this paradoxical dehydration still have to be discovered.

We measured the physiological changes in men exposed individually to survival situations which simulated the real thing as closely as was possible within the limits of common humanity and the experimental procedures. The subjects were exposed to only the physical aspects of a survival situation. Therefore, they were not subject to the anxiety and foreboding that weigh on a real survivor. For this reason, the value of the experiment is limited, since we can expect that a real survivor's state of mind would affect his body chemistry. But we can also expect that the body changes brought about by cold and starvation (which we measured) will greatly affect the state of mind.

- more -

During February, 1961, six men were set out at 200 yard intervals on the frozen surface of the Chena River near Fairbanks, Alaska. Each was dressed and equipped as if he had ejected from an airplane, except that he had no food. The subjects built shelters from their parachutes and generally conducted themselves along the lines recommended to aircrews by the survival schools of the U. S. Air Force. Since we wished to measure the effects of starvation, however, they were not permitted to trap or shoot animals. The temperature ranged between zero and 30° below zero Fahrenheit.

During 5 days of starvation under these severe conditions, the subjects' oxygen consumption rates were determined using specially modified portable equipment. From these measurements we found that the average daily energy cost was about 4000 Calories per man, or only that of a moderately hard day's farm work. The weight loss measured was much greater than would be expected from this energy debt alone, and we have concluded from our urine and blood analyses that the extra weight loss was from dehydration. This dehydration came about without any sensations of thirst and regardless of the water intake, since all the subjects were drinking as much melted snow as they wanted. The causes of this dehydration and possible means of combatting it will be an important part of future investigations.

Loss of body water and sodium causes a decrease in the circulating blood volume, and our results show that this certainly happened to our subjects. From this preliminary experiment we would suggest that the physiological (and psychological) repercussions of dehydration and the consequent decrease in blood volume are the most immediate hazards to a survivor in the arctic. They could lead to the death of the survivor before he experienced advanced starvation in the usual sense.

Two of the six subjects were arctic survival instructors of the U.S. Air Force. Three were medical students and one was an Assistant Professor of Physiology, all from Stanford. In the variables we measured, the experienced arctic men showed no significant differences from the unacclimated subjects from California.

$30,000 SCHOLARSHIP FOR MEMBER OF MEDICAL SCHOOL FACULTY

Dr. Herbert C. Schwartz, assistant professor of pediatrics at Stanford University School of Medicine, has been selected as a Scholar in Medical Science by the John and Mary R. Markle Foundation of New York.

Stanford will receive a grant of $30,000 to be used over a period of five years for the support of Dr. Schwartz and his research.

Dr. Schwartz has spent most of his professional life in the field of hematology, the study of blood. He was serving his medical residency at Stanford in 1955 when he discovered a new hemoglobin--termed G--then the fifth known. Hemoglobin is the red oxygen-carrying pigment in red blood cells.

This research stimulated his interest in hematology, and he spent the next five years, between 1955 and 1960, at the University of Utah as a research fellow in medicine and biochemistry.

He has been at Stanford since 1960. His major research interest now centers on the factors which affect manufacture of hemoglobin during the formation of the embryo and after birth.

Dr. Schwartz has published 19 technical papers in professional journals, many of them in the fields of hematology and pediatric research.

He was graduated from Yale University in 1948 and received his M.D. from the State University of New York in 1952.

Dr. Schwartz is one of 25 young medical scientists in the United States and Canada who were awarded scholarships by the Markle Foundation.

The Foundation has made annual grants since 1948 to relieve the shortage of faculty members in medical schools and to strengthen medical education.

STANFORD DERMATOLOGY DEPARTMENT MEMBERS TO RECEIVE TWO IMPORTANT AWARDS

A research associate and a resident in the Department of Dermatology will both receive important awards from scientific associations within the next month.

Dr. Victor R. Wheatley, research associate, will be given the Society of Cosmetic Chemists Special Award for 1962.

The citation accompanying the $1,000 award reads in part: "Dr. Wheatley is a highly gifted biochemist...(who has)... contributed greatly to our knowledge of the chemical composition of sebum (fat on the skin). One of his notable scientific achievements was the demonstration of provitamin D (the precursor of Vitamin D) in the epidermal cells. This was unsuccessfully looked for in the sebum by all previous investigators."

Dr. Wheatley, born and educated in England, received his bachelor's degree in 1947 and his Ph.D. in chemistry in 1950, both at the University of London.

The resident, Dr. Georgia Abrams, is receiving her $500 award through the Pacific Dermatologic Association for a paper submitted to the Nelson Paul Anderson Memorial Prize Essay Contest. Dr. Abrams has measured responses of skin temperature and blood flow to changes in environmental temperature.

Dr. Abrams, a native of Astoria, Ill., took a B.S. at the University of Illinois Pharmacy School in 1955, and her M.D. in 1959 at the School of Medicine of the same university.

NOTE TO EDITORS: The following story is timed for release after presentation of a research report at the annual meeting of the American Thoracic Society.

PHOTO AVAILABLE ON REQUEST

STANFORD SURGEONS TAKE FIRST STEP TOWARD HEART SURGERY OUTSIDE THE BODY

ST. LOUIS--Four Stanford surgeons reported today they have removed dogs' hearts for up to two hours, then replaced them without apparent harm to the animals.

The surgeons say their technique may be the first step toward operations in which a patient's heart is cut out of his body in order to correct serious heart defects.

This is the first time such experiments have been performed successfully, although surgeons have been trying to develop a suitable technique for such an operation for 50 years.

A report on the new development was presented this afternoon at the annual meeting of the American Thoracic Society by Dr. Edward J. Hurley, a postdoctoral research fellow at the Stanford University School of Medicine. Co-authors of the report are Eugene Dong, Jr., also a postdoctoral research fellow, Dr. Richard Lower, a surgical resident, and Dr. Norman E. Shumway, associate professor of surgery.

The procedure might be used in the next few years to treat a condition known as transposition of the great vessels, one of the common causes of "blue babies." At present there is no satisfactory operation for the ailment, in which the vessels carrying blood from the heart to the lungs and body are reversed.

The Stanford doctors said they cannot estimate how many children might benefit from the operation if it were perfected for patients. But they believe a large number of the 15,000 babies born each year in this country with inoperable heart conditions might be helped.

- more -

So far the experiments have been successfully carried out on four dogs which are still alive from five to nine months after the operations. Careful studies have shown no important damage to the heart's function.

The new technique depends in part upon a method of removing the heart developed two years ago by Dr. Lower and Dr. Shumway in their pioneering experiments in transplanting a whole heart from one dog to another.

Instead of cutting off each vessel separately, the surgeons leave part of the heart in place. This section receives all the veins leading to the heart. When the heart is returned to the animal, it is a simple matter to stitch the heart in place. With older methods, each vein had to be sewn together individually.

While the heart is out of the dog's body, it is kept in a cold (32 to 41°F.) salt solution to prevent death of the heart muscle. The dog is kept alive by a heart-lung machine.

Dr. Hurley said that the earlier transplantation experiments showed that hearts kept at low temperatures outside of the body for as long as seven hours would still function normally. However, the heart-lung machine causes chemical changes in the dog's blood and cannot be used for that long a period.

Dr. Hurley estimated that two to three hours would be available for corrective surgery of the heart while it is outside the body. The time the heart-lung machine is in use puts more of a limit on what can be accomplished in the way of heart surgery outside the body than the damage to heart muscle caused by lack of oxygen-carrying blood.

AIR FORCE CITES PALO ALTO-STANFORD HOSPITAL FOR OUTSTANDING PUBLIC SERVICE

The U.S. Air Force has cited the Palo Alto-Stanford Hospital Center "for outstanding public service" in training reservists of the 44th Casualty Staging Squadron, which has headquarters in San Jose.

The citation, a "Certificate of Patriotic Service," was presented to Hospital Administrator Oliver E. Deehan by Col. L.W. Hines of Santa Rosa, region surgeon for the Northern California area.

Men from the squadron spend two days each month in the Hospital, learning to be medical technicians. After a year's experience they are qualified to serve as orderlies in the Hospital, and fulfill their reserve obligations in this way.

In case of an attack, the squadron would be responsible for receiving casualties and administering medical care until the wounded could be airlifted out of the area.

The certificate commends the Hospital for providing "an outstanding public service to the United States Air Force" and for qualifying "these airmen to function in an operational ready capacity."

The other Air Force officer taking part in the presentation ceremony was Lt. Col. John L. Anderson of Mountain View, commander of the squadron.

Participating for the Hospital, in addition to Deehan, were Mrs. Darlene Lutts, director of nursing service, and Mrs. Peggy Gwinn, the nurse who has served as instructor for the squadron's training program.

STUDENT WINS $150 CONFERENCE AWARD FOR RESEARCH

Henry R. Hilgard, a senior student at the Stanford University School of Medicine, was awarded the $150 Palo Alto Medical Clinic prize for the outstanding paper presented at the second annual Stanford Student Medical Conference, it was announced today.

The day-long conference, sponsored jointly by the Stanford Medical Student and Stanford Medical Alumni Associations, was held April 6.

Hilgard's paper, "Polyvalent Immunological Tolerance," was based on his experiments in injecting chick embryos with spleen cells from other chickens. When hatched, the blood of the injected chicks, which ordinarily would have reacted against tissue from other chickens, was tolerant to these tissues.

This tolerance remained complete until the third week after hatching. By maturity, or the eighth week of life, however, the hatched chickens lost the tolerance.

Hilgard spent five months in Australia last year doing this research under Nobel Prize winner Sir Macfarlane Burnet at the Walter and Eliza Hall Institute in Melbourne. He used his summer vacation and the 12 weeks of free time allowed senior students in the Stanford medical school for the trip.

Hilgard is the son of Dr. and Mrs. Ernest R. Hilgard of Palo Alto. Dr. Hilgard is professor of psychology and education at Stanford. Mrs. Hilgard is acting associate professor of psychiatry in the medical school.

Other students presenting papers at the conference were Carol Sowers, a third-year student from Riverside, who discussed the value of periodic health examinations; Laurence Kedes, a senior from Hartford, Conn., whose paper dealt with the effect of decreased oxygen in the blood on various portions of the circulatory system; Ronald Poze, a senior from Palo Alto, who evaluated a test for opiate addiction.

- more -

Among other students presenting papers were Alexander Fefer, a third-year student from Brooklyn, N.Y., whose research concerned a new method of producing tolerance of adult mice to skin grafts; and Lawrence Eschelman, a third-year student from Represa, who reported on the effects of cutting sympathetic nerves upon blood flow in two major arteries after clamping the arteries.

Presentation of two clinical cases from the Palo Alto-Stanford Hospital Center were made by senior students. A case of mitral stenosis, a heart condition, was presented and discussed by Joseph Ellis of Chicago, Paul Jewett, Menlo Park, and Donald Doty, Los Angeles; and a case of disease of the small intestine by James Clever, Tracy, Victor Lavis, Los Angeles, and Laurence Kedes, Hartford, Conn. Lawrence Cohn of San Francisco, was chairman and moderator for both presentations.

Dr. Lewis Thomas, professor and chairman of the Department of Medicine, New York University School of Medicine, was the major speaker at the Conference. He discussed "The Future of Medicine as a Biological Science."

EDITORS: Parents' names and home addresses follow:

For release after 11:30 a.m. E.S.T. (8:30 a.m. P.S.T.), Monday, April 16, 1962.

NOTE TO EDITORS: The following story is timed for release after delivery of a research report at the annual meeting of the Federation of American Societies for Experimental Biology.

DEHYDRATION COULD CAUSE DEATH OF PILOT DOWNED IN ARCTIC, EVEN WITH WATER PLENTIFUL

ATLANTIC CITY--Can a man's body dry out even though he has all the water he wants to drink?

Under conditions of arctic survival this apparently happens, according to Dr. Terence A. Rogers and James A. Setliff of Stanford University School of Medicine.

The scientists are still puzzled as to why this occurs. But they said this paradoxical dehydration could cause a man's death before he really began suffering from starvation.

Dr. Rogers is assistant professor of physiology at Stanford, and Setliff is his laboratory assistant. They reported today on the first of a series of experiments conducted for the Air Force, which is interested in bettering the chances for a downed airman's survival in the bitter cold of the arctic.

The results were presented before the 46th annual meeting of the Federation of American Societies for Experimental Biology. They were based on measurements taken in February, 1961, when six men (three Stanford medical students, two Air Force arctic survival instructors and Dr. Rogers) camped out on the frozen Chena River near Fairbanks, Alaska, for five days.

Each man was dressed and equipped as if he had ejected from an airplane. Each built a shelter with his parachute. The temperature ranged between 0 and -30°F.

The men carried out the tasks usually associated with survival, such as gathering wood, but did not trap or shoot game since the object was to determine the effects of starvation. However, they could drink as much melted snow as they wished.

- more -

Weight loss for the men averaged 12 pounds. In every case it was more than the energy cost of the work done. The amount of energy expended was measured with portable equipment which recorded oxygen consumption.

Analysis of blood and urine samples indicates that the extra weight loss was due to dehydration. The drying out occurred even though the men noticed no extra sensations of thirst.

Further experiments will be carried out in the future to try to find out the specific cause of the dehydration, as well as methods of combating it.

The scientists concede that the experiments exposed the men to physical stresses only, and that the subjects were not faced with the psychological ones a real survivor would be.

"For this reason the experiments may be of limited value," Dr. Rogers said, "since a real survivor's state of mind would affect his body chemistry. But we can also expect that the body changes brought about by cold and starvation (which we measured) will greatly affect the state of mind."

Rogers and Setliff have recently conducted a second set of experiments in the arctic, again with medical students and Air Force survival instructors.

For release to a.m. newspapers of May 9, 1962.

NOTE TO EDITORS: The following story is timed for release following presentation of a research report at the 62nd annual meeting of the American Society for Microbiology.

NEW TEST EFFECTIVE IN DETECTING DANGEROUS "STREP" GERMS QUICKLY

KANSAS CITY, MO.--A new technique of identifying streptococcal bacteria which may lead to rheumatic fever and a serious kidney condition if not detected early can easily be put into widespread use for hospital patients, two Stanford University School of Medicine scientists reported yesterday.

The test takes less than two hours to carry out, while older methods commonly used take from two to five days. If the dangerous strain of bacteria is detected, treatment with the proper antibiotic can begin much sooner and patients will be protected from the serious diseases.

A report on the method, used for a decade in experimental laboratories but not successfully tried before on large numbers of patients, was presented before the 62nd annual meeting of the American Society for Microbiology.

Authors of the report were Dr. Helene C. Rauch, postdoctoral fellow in medical microbiology, and Dr. Lowell A. Rantz, professor of medicine at Stanford.

Rheumatic fever, which may cause permanent heart damage, and the kidney condition, glomerulonephritis, can occur as complications of "strep" throat infection or scarlet fever.

The complications may result within 10 days after diagnosis of the original infection, so prompt treatment is important, Dr. Rauch said.

Only one group of streptococci, known as group A, causes the complications. Other groups, however, may bring on strep throat.

-more-

The new technique uses a compound which fluoresces with a greenish glow under ultra-violet light. It is bound chemically with an antibody which reacts only to the A strain.

Antibodies are one of the body's main defenses against disease. The test uses antibodies from the blood of rabbits. Mixed with bacteria from the patient's throat, the fluorescent antibodies combine with the germs so they can be seen in an ultra-violet microscope.

Dr. Rauch and Dr. Rantz used the test on 767 persons with and without respiratory infections. They found it was 97 per cent effective in identifying the 160 patients with enough A germs to cause serious infections.

A comparison of results of this technique and the older method of growing the bacteria on a gelatin-like material until they become visible, indicated the new test was equally effective in detecting the germs.

The new method, known as the indirect immunofluorescent procedure, is just coming into use for diagnosis of rabies, whooping cough, and other diseases which were previously difficult to diagnose exactly in a short period of time. With the other diseases, the same fluorescent chemical is used, but with different antibodies.

HARD WORK AND NOT "HAPPY PILLS" WILL HELP THE MENTALLY ILL, PSYCHIATRIST SAYS

There will never be a Salk vaccine for mental illness.

Nevertheless, the public "blithely assumes that soon there will be a cure for our patients analogous to a cure for cancer."

These are the opinions of Dr. Don D. Jackson, director of the Mental Research Institute of the Palo Alto Medical Research Foundation and clinical associate professor of psychiatry at the Stanford University School of Medicine. His views appear in the current issue of the Stanford Medical Bulletin.

Dr. Jackson does not belittle the studies which have uncovered differences in body chemistry between certain mental patients, such as schizophrenics, and normal persons. Nor does he deny that tranquilizers and similar drugs have calmed mental patients and somewhat shortened their hospital stay.

But he feels that the emphasis on chemical aspects of mental illness does "discourage the public from facing the unpleasant facts about the administration and treatment of mental disorders." He stresses that the public and the medical profession must not lose sight of "those simple human measures that will be effective in helping the emotionally disturbed."

Each year we rediscover the fact that mental disorders, including schizophrenia, arise out of personal relationships, Dr. Jackson continued. We fill out the rest of the year "with dreams of glory about the biochemical cause of schizophrenia, and new happy pills. We somehow fail to keep in mind the analogy that 99 per cent of headaches develop as a result of social situations (and here I include hangovers); yet this does not dispute the fact that aspirin is a good remedy."

"All of us are only too eager to deny an effect on our children and others around us... It is small wonder that parents are intrigued by hereditary and chemical explanations of their child's emotional problems..."

- more -

As an example of one simple human measure that worked, Dr. Jackson cited the case of a director of a mental hospital in Stockholm, who took 50 patients on a vacation to Italy. "The senile dementia patients were not much helped by the change of scene, but eight patients with various forms of schizophrenia, all of whom had been hospitalized for more than 15 years, were permanently discharged after the group returned to Stockholm."

Senile dementia is the deterioration of intelligence in old age. Schizophrenia is the most severe and widespread form of mental disturbance. It is characterized by a loss of the sense of reality and leads to withdrawal into a fantasy world.

An innovator like the Stockholm doctor faces "sizeable odds," Dr. Jackson admitted. "He must fight an inertia in staff and administration that stems partly from waiting for the chemist to invent a pill that will take the hard work out of caring for the mentally disordered."

Dr. Jackson offered some solutions to the problems of caring for patients. We must stop building great stone and steel mausoleums far from town in order to care for the mentally disordered, he suggested. "We know that the less rupture that occurs between the mental patient and his status quo, the more quickly and effectively he can resume his usual place in society."

The type of facility Dr. Jackson prefers is a small unit of about 20 patients in a fairly old house, close to the patients' homes. "Although such a facility sounds expensive, the brevity of the patients' stay might more than make up for the greater daily cost."

Furthermore, mental facilities are not adequately staffed. Very few state legislatures vote enough funds for the support of a sufficient number of trained personnel, Dr. Jackson said.

"A hospital might deliberately choose to concentrate the bulk of its staff on promising patients and face the criticism that such a move would evoke. Good results might influence the legislatures."

"For the sake of expediency, policies are enacted that are demeaning to the human spirit. Treat a patient like a child and he will stay a child--at the taxpayer's expense."

"In addition, we must pay more attention to where the patient comes from and where he will be returning when he leaves the hospital," he emphasized. "It is conceivable that if psychiatrists were not traditionally tied to their chairs, the proper place to interview most patients who are slated for hospital entry would be in their own homes."

MEDICAL STUDENTS WIN AWARDS FOR TOP SCHOLARSHIP

STANFORD - Ten senior medical students at Stanford University's School of Medicine received awards for superior scholarship at the Convocation for the Class of 1962 Saturday (JUNE 16). Also honored were a third-year medical student and an intern at Palo Alto-Stanford Hospital.

Lawrence H. Kedes, "whose research during his undergraduate career in the Stanford Medical School is deemed most meritorious," received the $500 Borden Undergraduate Research Award. Kedes'research involved studies of the effects of reduced oxygen supply on the hearts and blood vessels of laboratory animals. He also was one of five senior medical students who received a Mosby Scholarship Book Award.

The Hopkins award of $100 went to senior student Armar A. Strauss for outstanding work in dermatology.

Others who received the Mosby Scholarship Award, which provides a selection of any one Mosby publication with a value up to $30, were Lawrence S. Barnett, Lawrence H. Cohn, Donald B. Doty and Victor R. Lavis.

Winners of the Merck Manual Awards were Paul K. Johnson and Demosthenes Pappagianis.

Alan T.C. Lee won the Robert T. Legge Award, given by the Northern California Chapter of the American Industrial Hygiene Association to a senior who shows the most aptitude and interest in the study of preventive occupational health. The award was a book of the recipient's choice. Senior Sara Jean Christensen received an honorable mention citation from the American Medical Women's Association for her high scholastic achievement.

- more -

The Julian Wolfsohn Award of $100 went to John M. Simpson Jr., M.D., the intern who during the year did the best work in internal medicine and neurology.

The Roche Award of an engraved Omega wrist watch was given to Alexander Fefer, selected as "the outstanding student of medicine who has successfully completed the first three years of medical school."

Dr. Robert H. Alway, dean of the Medical School, administered the Hippocratic oath, and Dr. Roy B. Cohn, acting executive of the Department of Surgery, addressed the graduates. Dr. Seymour Kolko, assistant dean for student affairs, presented the awards.

* * * * * * * * * * *

EDITORS: Students and their parents listed below:

LAWRENCE H. KEDES - son of Mr. and Mrs. Samuel E. Kedes, 81 Hebron St., Hartford, Conn. He and his wife live at Escondido Village, Stanford.

ARMAR A. STRAUSS - lives at 723 Valparaiso, Menlo Park.

LAWRENCE S. BARNETT - son of Mr. and Mrs. S.R. Barnett, 651 Vistamont, Berkeley. He and his wife live at 540 University Dr., Menlo Park.

LAWRENCE H. COHN - son of Mr. and Mrs. Harold E. Cohn, 39 Sea Cliff Ave., San Francisco. He and his wife live at 750 Coleman Ave., Menlo Park.

DONALD B. DOTY - son of Mr. and Mrs. Ben M. Doty, 3330 Charleston Way, Los Angeles. He and his wife live at 880 Roble Ave., Menlo Park.

VICTOR R. LAVIS - son of Mr. and Mrs. Salvo Lavis, 545 S. Gramercy Pl., Los Angeles.

PAUL K. JOHNSON - son of Mr. and Mrs. O.M. Johnson, 225 12th, Casper, Wyo.

DEMOSTHENES PAPPAGIANIS - son of George Pappagianis, 704 I St., Chula Vista. He and his wife live at 409-4 Stanford Village, Stanford.

ALAN T.C. LEE - son of Mr. and Mrs. Harry Y.S. Mau, 3742-A Old Pali Rd., Honolulu, Hawaii.

SARA JEAN CHRISTENSEN - daughter of Mrs. Janet Christensen, 214 Wilson Ave., Oildale.

JOHN M. SIMPSON JR., M.D. - and his wife live at 474 Waverly, Menlo Park.

ALEXANDER FEFER - son of Mr. and Mrs. Joseph Fefer, 182 E. 56th St., Brooklyn, N.Y. He and his wife live at Escondido Village, Stanford.

CONFERENCE ON SPORTS MEDICINE AND PHYSICAL FITNESS SET AT STANFORD JULY 18-20

What is hoped to be the first Russian-American Conference on Sports Medicine and Physical Fitness ever held is being planned at Stanford University July 18-20, it was announced today.

The conference is scheduled Wednesday through Friday immediately before the major Russian-American Track and Field Meet July 21 and 22 in Stanford Stadium.

Several leading American specialists have agreed to participate, and invitations have been extended to two outstanding Russian experts in physical culture.

Emphasis will be on physiological factors in sports and fitness, and on methods of evaluating physical fitness and exercise programs.

July 19 will be devoted to a symposium for physicians and scientists. On July 20 sessions will be held for coaches and physical education specialists. A closed conference for the invited speakers in planned July 18.

The Russians invited to participate are Dr. M. F. Ivanitsky, the author of several texts about physical culture, and Dr. A. V. Korobkov of the Institute of Physical Culture in Moscow.

American participants will be Steven M. Horvath, professor of physical education at the University of California, Santa Barbara, who is noted for his research on the responses of trained and untrained individuals to exercise; Dr. Hans Kraus, associate professor of clinical physical medicine and rehabilitation at New York University, who has conducted comparative studies of fitness in American and European children; Dr. William Hunter of the Permanente Medical Group in San Francisco, who specializes in the care of muscular and skeletal disorders; and Dr. Daniel J. Feldman, director of the Division of Rehabilitation Medicine at Stanford Medical Center.

Dr. Feldman is coordinating planning for the conference, which is being financed by the Cummings Research Foundation of Beverly Hills, Calif., and the U.S. Olympic Committee.

Physicians and coaches interested in attending sessions should contact Dr. Feldman by writing him at Stanford Medical Center, Palo Alto, California.

STANFORD MEDICAL CENTER NEWS BUREAU
Palo Alto, California

FOR FURTHER INFORMATION CONTACT: Samuel Moffat, DA 1-5310

FOR RELEASE TO A.M. NEWSPAPERS OF JUNE 8, 1962. (Release time set by the National Institutes of Health, which are issuing an announcement for simultaneous release.)

TWO CLINICAL RESEARCH CENTERS TO BE ESTABLISHED AT STANFORD MEDICAL SCHOOL

Two new research centers for the investigation of human diseases--including the first ever established by the National Institutes of Health for the study of premature infants--will be set up at Stanford Medical Center with grants totaling $797,305 announced by the United States Public Health Service today.

The new grants make Stanford University School of Medicine the first medical school in the country to have three NIH-supported clinical research centers. Investigations of new methods of treating cancer with X rays and other radiation are already under way with a $943,412 federal grant announced last year.

The premature infants' study will be financed with a $267,305 grant. The remaining $530,000 will support a general research facility in which certain major problems such as tissue grafting, growth and development, function of the nervous system, and resistance and susceptibility to infection will be attacked over several years.

The government expects to support the research centers for a minimum of seven years, but allocations have to be made on a yearly basis depending upon the availability of funds. The prematurity center is expected to cost about 1½ million dollars to support over this period, the general center approximately 4½ million dollars.

First patients will be admitted to the Clinical Research Center for Premature Infants after August 1. Investigators in many departments of the medical school will take part in patient care, research and teaching there.

There will be major emphasis on the use of electronic equipment, of the type developed for the man-in-space program, to continuously record each infant's heartbeat, brain waves, basal metabolism, and other evidences of bodily function.

- more -

Prematurity poses critical problems in medicine. In the United States more than half of all deaths in the first month of life are due to premature birth. This high mortality rate persists despite the widespread advances in medical science in the last 25 years.

The physicians hope their findings will lead to developing methods for reducing not only mortality, but the high incidence of mental retardation, nervous disorders and birth defects in these children.

Principal investigator will be Dr. Norman Kretchmer, executive head of Stanford's Department of Pediatrics. Program director will be Dr. Sumner Yaffe, assistant professor of pediatrics. The unit will have space for six bassinets as well as its own laboratory facilities.

The General Clinical Research Center will open in midwinter with 16 beds. The purpose of the unit is to provide an opportunity for controlled study of human diseases so that basic scientific principles can be applied to study and care of patients.

There will be beds for metabolic studies of children, for neurologic investigation with facilities for continuous recording of brain waves and similar electrical measurements in patients, and for general use. Six of the general beds will be in isolation rooms for patients with infections or who are very susceptible to infections because of their serious ailments.

Dean Robert H. Alway of the medical school is to be principal investigator. Program director for the unit will be Dr. Stanley L. Schrier, assistant professor of medicine.

The grants for both centers cover full hospitalization expenses of patients who are admitted to the units. This is expected to remove a major obstacle to the quick application of the latest medical findings to patients, since detailed studies necessary are usually far too expensive to be paid for by patients themselves.

NOTE TO CITY EDITORS, SCIENCE WRITERS AND SPORTS EDITORS

We have scheduled a news conference at 1:30 p.m. Wednesday, July 18, here at Stanford Medical Center, with the participants in the Russian-American Conference on Sports Medicine and Physical Fitness.

The news conference will be held in the Dean's Conference Room of the School of Medicine. If your reporter and/or photographer will come to the information desk in the main lobby of the hospital, the information clerk will direct them to the room.

About a dozen members of the conference will be present. They are experts in physiology, medicine, physical education, with particular emphasis on sports and physical performance. Expected to attend are Dr. A.V. Korobkov of Moscow's Institute of Physical Culture and Dr. M.F. Ivanitsky, author of physical culture books.

Americans include: Steven M. Horvath, professor of physical education at the University of California, Santa Barbara, who is noted for his research on the responses of trained and untrained individuals to exercise; Dr. Hans Kraus, associate professor of clinical physical medicine and rehabilitation at New York University, who has conducted comparative studies of fitness in American and European children; Dr. William Hunter of the Permanente Medical Group in San Francisco, who specializes in the care of muscular and skeletal disorders; and Dr. Daniel J. Feldman, director of the Division of Rehabilitation Medicine at Stanford.

Also: Dr. Donald L. Stillwell, Jr., associate professor of anatomy at Stanford; Dr. George Feigen, associate professor of physiology at Stanford; Dr. Frederick L. Behling, clinical instructor in surgery at Stanford; Franklin Henry, professor of physical education at the University of California at Berkeley; David Clark, University of California at Berkeley; and Dr. Ernst Jokl, professor of physiology at the University of Kentucky, and president of the International Council of Sports and Physical Education.

Sandwiches will be served at 1 p.m. for those who may not be able to get lunch because of the early hour in the afternoon. Please let us know if your staff member will want lunch so we can order enough sandwiches.

FOR IMMEDIATE RELEASE

STANFORD - Can what is useful also be beautiful, in the special sense that art is beautiful? When is design art? Stanford University's Art and Architecture Department is exploring these questions at its summer session this year and sharing the search in a series of public lectures.

The next program will be at 8 p.m. Wednesday (JULY 18) in Cubberley Auditorium when Donald H. Short, studio director of the Walter Landor and Associates industrial design firm, will discuss design as a problem solver.

His talk will cover the function of the industrial designer as well as creativity and design philosophy. The lectures will be augmented with slides on design in general and on specific examples of the firm's work, plus an 18-minute documentary film of an actual design project.

Short is a past president of the San Francisco Society of Designers and Illustrators, a member of the San Francisco Art Association advisory committee for the San Francisco Art Institute, and a lecturer on industrial design at San Jose State College and the Management Development Center, University of San Francisco.

In addition to their public programs, the off-campus lectures for this series each spend two days with Stanford art students--answering questions, criticizing work, bringing new ideas.

The remaining free public lectures this summer are at the same hour and place. On July 25 Stanford Art Prof. Matt Kahn continues the search for values in identifying beauty in the useful, with a discussion of art components. On Aug. 1 the speaker will be David Campbell, practicing architect and president of the American Craftsmen's Council, New York. On Aug. 8 trends in design will be the subject for Mildred Constantine, associate curator of design at New York's Museum of Modern Art.

OPEN-END DISCUSSION TO BE FEATURE OF CONFERENCE ON SPORTS MEDICINE AND PHYSICAL FITNESS

The Russian-American Conference on Sports Medicine and Physical Fitness to be held at Stanford University July 18 and 19 will feature an open-end discussion Thursday.

The Thursday meeting will begin at 9 a.m. in Dinkelspiel Auditorium. Coaches, athletic directors, physicians and others interested in physical education and sports medicine are invited to attend. Pre-registration is unnecessary and there is no attendance fee for the meeting.

Originally planned for July 18-20, the conference now will take place on July 18 and 19. On Wednesday there will be a closed conference for participants. Discussions during both days will center around the physiological factors in sports and fitness and methods of evaluating fitness and exercise programs.

The conference will be held before the major Russian-American Track and Field Meet July 21 and 22 in Stanford Stadium. Participating will be American experts and Dr. M.F. Ivanitsky, author of several books on physical culture, and Dr. A.V. Korobkov of Moscow's Institute of Physical Culture.

The Robert Cummings Foundation of Beverly Hills, Calif., and the U.S. Olympic Committee are financing the conference, which is believed to be the first one bringing together U.S. and U.S.S.R. experts in physical culture.

$493,645 GRANT TO CONTINUE RESEARCH ON DISFIGURING SKIN DISEASE

Stanford University School of Medicine's intensive investigation of psoriasis, the disfiguring skin disease which affects 3 to 4 million Americans, will continue for another three years under a grant of $493,645 from the John A. Hartford Foundation, Inc., of New York, it was announced today.

Scientists have studied the course of the ailment in more than 450 patients at Stanford Medical Center since 1959, when the program was started with an initial grant of $295,928 from the Hartford Foundation.

At present the cause of psoriasis is unknown. Treatment is on a trial-and-error basis and may partially relieve symptoms but there is no cure, according to Dr. Eugene Farber, executive head of the Department of Dermatology at Stanford and director of the research.

During the investigation intricate chemical analyses of fatty substances and proteins in many patients' skin (both normal and diseased) have been made in an attempt to learn more about the cause of the illness, what its specific characteristics are and how it relates to other diseases. New drugs and new ways of administering medication have also been tried.

Psoriasis is a chronic condition characterized by the eruption of round, red patches covered by white scales. The patches usually occur on the elbows, knees, scalp and back; at times they may cover the entire body. It has been estimated that the ailment affects 2 per cent or more of the world's population.

Thus far the multi-discipline attack has utilized specialists in chemistry, pathology, genetics, immunology, physiology and rheumatology. Working with Dr. Farber are Dr. Alvin J. Cox, executive head of the Department of Pathology; Eve P. Reaven, Donald Eddy, and Joseph Peterson, research assistants; and three new members of the Stanford faculty, Marvin A. Karasek, assistant professor of biochemistry in dermatology, and Research Associates Frank Grauer and Ian Wilkinson.

The Hartford grant will count toward the campaign total in the current Stanford PACE Program -- a $100 Million Plan of Action for a Challenging Era. The gift will bring the University an additional $164,548 under a matching grant from the Ford Foundation, which provides $1 for every $3 received from other private sources.

- more -

Future projects planned under the Hartford grant include the following:

1. Continued collection of data from patient histories, which now record on punched cards the course of the disease in more than 500 patients in the United States and abroad. "We are now able to compare psoriasis as it exists in various regions of the United States and in some foreign countries," Dr Farber said.

As the amount of data grows it will be possible to study the frequency of disease in terms of age, sex, family, race, presence of arthritis or other ailments often seen with psoriasis, presence of the latent form as compared with the active one, and so on.

2. The use of skin transplants to find out why some diseased skin will remain abnormal when moved elsewhere on the body or will revert to normal form; and why normal skin will sometimes become psoriatic when moved to a diseased area and sometimes will not.

3. Studies of unusual forms of the disease -- inside joints, on skin surfaces inside the elbows and knees instead of outside, those brought on by administration of drugs such as certain hormones or medication for malaria, and those aggravated by ultraviolet light, which is usually beneficial.

4. Examination of the relationship with disorders commonly found among psoriasis patients, including gout, diabetes, rheumatoid arthritis, high blood pressure and obesity.

5. Continued studies of new drugs, both for application to the skin and for administration by other means.

6. Continued laboratory studies using techniques of immunology, electron microscope examination, growth of tissue in test tubes, biochemistry, and the like.

HOFFMAN NAMED ASSOCIATE ADMINISTRATOR FOR FINANCE AT PALO ALTO-STANFORD HOSPITAL CENTER

Arthur J. Hoffman has been named associate administrator for finance at the Palo Alto-Stanford Hospital Center.

Business manager since May, 1959, Hoffman fills the vacancy created by the resignation of Walter R. Rentschler. In September, Hoffman will take over the position formerly held by William J. Moir. At that time the jobs of the various associate administrators, with the exception of Hoffman, will be reassigned.

Hoffman received a bachelor of science degree in business administration from the University of California at Berkeley in 1938. He then spent six years in the Finance Corps of the U.S. Army, mainly in Juneau, Alaska, and Lexington, Ky. At the time of his discharge, he held the rank of lieutenant colonel.

He entered the hospital field in 1949. For six years he was the business office manager at the Washoe Medical Center, Reno. After that he spent more than a year as administrator of the Carson-Tahoe Hospital, Carson City, Nev.

Last January he was elected vice president and program chairman of the Northern California Chapter of the American Association of Hospital Accountants.

Hoffman and his wife, Muriel, have been married for 20 years. They have three children: Michael, 17, Susan, 14, and Nancy, 9. They live in Santa Clara.

TWO STANFORD MEDICAL STUDENTS TO BE FIRST FROM U.S. TO JOIN PROJECT HOPE

Two Stanford students will be the first medical students from the United States to work with Project Hope, the floating people-to-people medical center now in Trujillo, Peru.

Ernest Altekruse of Ft. Wayne, Ind., and John Howell of Rochester, Minn., both fourth-year students, will spend five weeks with the Project. They hope to join the hospital ship late this month. At present they are trying to interest donors in financing their flights, each of which costs about $650 round trip. Room and board will be furnished by the Hope.

In addition to assisting the Project in bringing modern medical skill to Peruvian patients, Altekruse and Howell would like to establish the first exchange between U.S. and Peruvian medical students.

"Officials in Peru have expressed great interest in such an exchange," said Dr. Theodore M. Myers, a Stanford alumnus who practices in San Mateo and is a clinical instructor in the Stanford Medical School.

Along with other volunteers this spring, Dr. Myers set up the Hope's program in Trujillo, an area with few doctors. Before going to Peru, Dr. Myers spoke to Stanford Medical School classes to see if students were interested in joining the Hope.

"I thought the Project was something that everyone else could do, but not me," Howell said. "Then Ernie (Altekruse) really sold me on the idea. It will be a great adventure and will give us the opportunity of doing many things at once. It's about the best thing that could possibly happen."

2

- more -

The two will work closely with Peruvian students and doctors on the ship, in the community and at Trujillo's new medical school. They will assist in deliveries, give vaccinations and help doctors in outpatient clinics in neighboring villages. "They will gain experience themselves and will perform an important service," said Dr. Myers.

Altekruse, 34, is an ex-Marine major and the father of six children. He and his wife met and married while both were in the Marines. Then they decided to go to medical school. Altekruse had become interested in medicine while writing a thesis on medical electronics at the Naval Postgraduate School in Monterey. His wife received her M.D. degree in 1960. Altekruse is the son of Mr. and Mrs. Fred B. Altekruse, 2604 Sherman Blvd., Ft. Wayne, Ind.

Howell, 29, a bachelor, also has a background in electronics. He received a bachelor's degree in electrical engineering from the University of Minnesota, after having earned another bachelor's degree in biology at the California Institute of Technology. This summer before going to Peru he is working in the surgical pathology laboratory at the Mayo Clinic, Rochester, Minn. He is the son of Dr. and Mrs. L.P. Howell, 1099 Plummer Circle, Rochester. His father is a member of the Mayo Clinic Staff.

Samuel Moffat (DA 1-5310 or UL 1-0103)

FOR RELEASE AT 10 A.M. (P.D.T.) SEPT. 22, 1962. This story supplements a simultaneous announcement from NASA in Washington, D.C.

The National Aeronautics and Space Administration (NASA) today announced a $535,000 grant to establish a biomedical instrumentation laboratory at Stanford Medical Center.

The new facilities will permit a fourfold expansion of research efforts at Stanford University School of Medicine in the fields of space biology and biomedical instrumentation. Investigators hope to design devices which can detect life--if any--on Mars and other planets. They also anticipate that the techniques they develop may have broader applications in the fields of biology and medicine.

Research in this field is already under way at Stanford under a three-year $380,640 grant from NASA. It is being directed by Dr. Joshua Lederberg, Nobel Prize geneticist who heads Stanford's Department of Genetics. Associated with Dr. Lederberg and responsible for the instrumentation aspects of the program will be R. Elliott Levinthal, formerly president of Levinthal Electronics Products, Inc.

The biomedical laboratory will be located in a new $5.5 million Clinical Sciences Building which is expected to be ready for occupancy in 1964. Instrumentation laboratories and shops will be on the ground floor; biological applications will be studied on the third floor in an area adjacent to the recently announced $1 million Lt. Joseph P. Kennedy, Jr., Laboratories for Molecular Medicine.

The NASA-provided facilities will occupy approximately 10,000 square feet in the building. It is expected that cooperative research programs will be set up with other scientists throughout the medical school.

The grant is one of the first research facilities grants ever to be authorized by NASA. Other grants, announced simultaneously in Washington, went to the University of California (Berkeley), University of Chicago, Rensselaer Polytechnic Institute and the State University of Iowa.

ANNOUNCEMENT OF NEWS CONFERENCE

Six months ago a team of Stanford surgeons, working at the Veterans Administration Hospital in Palo Alto, successfully cleaned out a completely blocked coronary artery which had crippled a 47-year-old VA patient. The patient has recovered so well that he is now ready to return to work as a laborer.

The surgeons used a new technique for the operation and for the first time with such an operation have X-ray photographs to show that the artery was completely blocked before surgery, but is now open and functioning normally.

Details of the operation will be explained at a joint Stanford-VA news conference at 10:30 a.m. Thursday, Nov. 1, 1962. The conference will be held in Building 1 (the main administration building), Room 1-A-513, Veterans Administration Hospital, 3801 Junipero Serra Blvd., Palo Alto. The hospital is located between Page Mill Road and Arastradero Road; best roads by which to reach it from Bayshore Highway are Oregon Avenue (which becomes Page Mill) or Charleston Road (which becomes Arastradero).

The patient, the surgeon and the internist who directed the difficult preoperative diagnostic tests will attend the conference. Color movies of parts of the operation will be shown and the whole procedure will be carefully explained. Copies of the X rays before and after surgery will be available. John J. Prusmack, M.D., director of the Veterans Administration Hospital, will serve as moderator. You are invited to send a reporter and/or photographer.

COLLIES AT STANFORD MEDICAL CENTER AID RESEARCH ON EYE CONDITION

Several dozen collie dogs at the Stanford Medical Center are helping scientists study an eye condition which has been affecting more and more Americans each year.

Collies are the first known animals in which the condition -- detachment of the retina -- occurs naturally. The degenerative condition found in the collies' eyes is similar to a defect which blinds many Americans each year.

Because of the extended life span in the U.S., an increasing number of persons over 50 develops retinal detachment. Statistics on it are sketchy, but the doctors estimate that five percent of the blind population may have retinal detachment.

The study is directed by Dr. Seymour R. Roberts, a veterinarian and research associate at Stanford University School of Medicine, and Dr. A.N. Dellaporta, assistant professor of ophthalmology.

"It is well known that animal and human eyes have much in common and frequently the findings in animal eye disease can be applied to human eye disease," said Dr. Roberts. "For the first time, retinal detachment can be added to the list of diseases whose study may aid the ophthalmologist in the search for new methods of preventing blindness in humans."

According to Dr. Roberts, the studies of the Stanford collies also provide information for breeders and dog lovers. He is afraid that since the condition in collies is congenital, the defect may influence the entire breed.

"At present, about 30 percent of all the collies in the U.S. have eye defects. Half of those affected probably will develop detachment, with blindness resulting in a large number."

- more -

"Dog lovers apparently are unaware of the seriousness of this condition," Dr. Roberts continued. Collies are the seventh most popular dog in the U.S., according to the American Kennel Club's registrations. More than 6,000 collies may be affected.

Dr. Roberts suggests that all breeding stock be examined and dogs with detachment eliminated from breeding strains. "Recognition of the defect is not easy for veterinarians not trained in diseases of the eyes. This is perhaps one reason why the defect has gone unrecognized this long and breeding of affected dogs has continued."

Dr. Dellaporta said that the majority of retinal detachments, in both humans and collies, increase in frequency with age. "In every detachment," Dr. Dellaporta continued, "there is a defect in the back of the eye, although this can be too small to be detected in each case. A tear or hole is caused in the retina, and fluid escapes between the retina and the choroid, the vessel-bearing membrane. The retina loses its nourishment and degeneration follows. In extreme cases the tissue shrinks and no longer conforms to the shape of the eye."

Preliminary treatment of retinal detachment is bed rest, so the detached part settles down again. Then an artificial inflammation is created around the hole, by high frequency electric current, chemicals, electrolysis or intense light. "The ensuing scar formation seals the hole so that no fluid can escape," said Dr. Dellaporta. In complicated cases, more radical means such as surgical shortening of the eyeball must be used.

The doctors hope to learn the following from the collie study:

1) How the defect in the collies, which produces a congenital detachment, is transmitted. This will be done through various breeding methods.
2) How study of the disease in collies may give the doctors hints about the course of the human disease and its prevention.
3) How to develop more efficient methods for curing the condition in humans.

Dr. Dellaporta specializes in the surgery of retinal detachment and Dr. Roberts, president of the American Society of Veterinary Ophthalmologists, has a private practice in Richmond (Calif.). The two have been studying the defect for more than three years at Stanford, supported by the National Institutes of Health.

WEST'S 1ST RESEARCH PROGRAM IN CHILDHOOD APHASIA STARTS AT STANFORD MEDICAL CENTER

The West's first research program in childhood aphasia is getting under way this week at the Stanford Medical Center.

Funds for the Scottish Rite Institute for Childhood Aphasia are being provided for by the Scottish Rite Foundation of California. The foundation contributed $22,200 as an initial grant for starting the program and will donate funds for continuing it.

The institute is being housed temporarily in the renovated "nurses' cottage" at the Palo Alto Hospital. Members of the institute staff will study childhood or congenital aphasia. An aphasic child is unable to speak or to learn to read and write as a result of brain damage. The number of aphasic children in the country has not been determined because the condition is often confused with other ailments.

Directing the institute's activities is Dr. Jon Eisenson, an internationally known expert on aphasia. A leading authority and investigator in speech pathology, Dr. Eisenson is the author of more than a dozen books in the field and has contributed numerous articles to professional journals.

Before coming to Stanford this fall he was professor and director of the speech clinic at Queens College, N.Y., and a lecturer at the College of Physicians and Surgeons, Columbia University.

He is a past president of the American Speech and Hearing Association. Dr. Eisenson received a B.S. in Social Science from the College of the City of New York and M.A. and Ph.D. degrees from Columbia.

"This will be the first program in the West -- and one of few in the country -- especially devoted to training and testing our theories and approaches to the problem of childhood aphasia," Dr. Eisenson said.

- more -

"There are a few treatment centers elsewhere in the U.S. but this one will be the most comprehensive research program in the West.

"In a world where communication has become increasingly important, the child who has not learned to speak is severely handicapped. Aphasic children often appear to be mentally retarded, hard-of-hearing or emotionally disturbed. Yet carefully administered tests may show that a child is intelligent enough to carry out tasks which do not depend upon language."

During the center's initial stage, two or three children up to age 13 will be accepted for diagnosis and evaluation at any one time. The evaluation period may last from 3 to 10 days. Each child admitted for diagnosis will receive an examination by a pediatrician, a neurologist and a psychologist, as well as by speech and hearing specialists.

After screening, 10 to 15 pre-school youngsters with established neurological difficulties will be selected for long-term training. This training may take from one to three years.

Specific goals for the project include:

1) Detailed study of the behavior and language impairment of aphasic children in an effort to increase the effectiveness and accuracy of diagnosis.
2) The development of special techniques to teach aphasic youngsters to speak and understand language.
3) Investigations to pinpoint the learning problems associated with brain injury.
4) Counseling and guidance for parents whose children cannot be accepted for training but who will be referred to other agencies.
5) The training of teachers and speech therapists to work with aphasic children.

The Childhood Aphasia Institute was established under the auspices of the School of Medicine's Division of Speech Pathology and Audiology. Staff members of the institute will work closely with other departments at the Medical Center.

Further information may be obtained by calling the Division of Speech Pathology and Audiology.

NOTE TO EDITORS: The following story is a joint announcement of the Stanford University School of Medicine and Varian Associates.

NEW MEDICAL LINEAR ACCELERATORS INSTALLED AT STANFORD AND UCLA

A gleaming new version of Stanford University's once experimental medical linear accelerator, now a valued tool in the treatment of many forms of cancer, is in use at Stanford Medical Center and the University of California Medical Center in Los Angeles today.

The two $150,000 machines are the first commercial models of the accelerator off the production line of Varian Associates, Palo Alto (Calif.) electronics firm.

"The medical linear accelerator has led to real advances in the treatment of several forms of cancer," according to Dr. Henry S. Kaplan, executive head of the Department of Radiology at Stanford University School of Medicine.

Dr. Kaplan and Dr. Edward L. Ginzton, former director of the Microwave Laboratory at Stanford, directed design and construction of the first medical unit by Stanford physicists. It was installed in the medical school in San Francisco late in 1955, and the first patient was treated in January, 1956. It was moved in 1959 to Stanford Medical Center in Palo Alto, where it is still in daily use.

- more -

In nearly seven years the medical unit has been used to treat more than 1500 patients. The 6-million-electron-volt (6 MEV) supervoltage X-ray beam penetrates to certain deep-seated tumors which are difficult or impossible to remove by surgery. It also reduces the skin reaction caused by radiation, so that a higher dose may be given than with conventional (250-thousand-electron-volt) X-ray equipment.

While many different sorts of tumors have been treated, Dr. Kaplan said that the most significant improvements in results to date have been noted in cancers of the bladder, prostate, tongue, throat, and sinuses, and in malignant tumors of the lymphoid tissues, such as Hodgkin's disease.

Even if it had not achieved better end-results, supervoltage therapy would still be valuable simply because it entails far less discomfort for patients. Reactions of the skin from the radiation are usually absent, nausea and loss of appetite are minimized, and there are few complications after treatment.

(Cobalt units, using X rays from radioactive cobalt, also produce supervoltage radiation. But the accelerator has a higher output which makes treatments shorter and thus more comfortable for the patient. The difference in output increases as the cobalt decays over a period of time. The electronic device also produces a sharper beam which is not as likely to affect normal tissue near a tumor.)

Dr. Kaplan cautioned, however, that the accelerator is not necessarily suitable for treatment of all types of cancer. For this reason, Stanford has a policy of accepting patients only on referral from their own physicians. "After consultation with his or her physician, we are better able to judge whether supervoltage radiation or more conventional therapy will be best for each individual patient," he said.

He also warned that many more years' experience will be needed before the value of supervoltage radiation can be fully appraised. "Although we are very definitely encouraged thus far, much larger numbers of cases will have to be observed over long periods of time for final evaluation of the new techniques which supervoltage equipment has made possible in cancer treatment."

Construction of the first Stanford medical accelerator was made possible by grants from the American Cancer Society and the National Cancer Institute of the U.S. Public Health Service. Construction of the heavily shielded treatment room for the new accelerator was aided by a new grant from the National Cancer Institute.

The new unit is being used in connection with the N.C.I.-supported Clinical Radiotherapy Cancer Research Center in which new methods of treatment with radiation are being devised and tested.

The Varian machine, called the Clinac, has several unique features. The unit may be rotated 360° about the patient to spread the skin exposure while the beam is aimed directly at the tumor during the full treatment.

Varian's Clinac is the first commercial medical linear accelerator of its type made in the U.S. Three British firms manufacture medical accelerators, but none are in use in this country.

The original Stanford machine was the first medical accelerator in the Western Hemisphere. Since then two others have been set up (at the University of Chicago and Michael Reese Hospital in Chicago), but neither features the movable tube characteristic of the Stanford model.

The medical accelerator is a scaled-down version of the University's one-billion-electron-volt (1 BEV) machine used in nuclear research. The large accelerator was used in the pioneering studies of Professor Robert Hofstadter of Stanford, who won the 1961 Nobel Prize in physics for making the most accurate measurements of the size of the neutron and proton.

The medical accelerator is also a relative of the 2-mile-long linear accelerator which is now being built on the Stanford campus. When that machine is finished in 1967 it will be the world's largest, with an output of 20 BEV.

Dr. Ginzton, now chairman of the board of directors for Varian Associates, directed planning for the 2-mile-long accelerator prior to its authorization by Congress in 1961. He has been on leave from Stanford since 1961, devoting all his time to Varian.

In all of these machines, tiny charged particles known as electrons are speeded up by pulses of high-frequency radio waves until the electrons reach nearly the speed of light. Even in the relatively short five-foot tube of the new medical unit the particles reach the 6 MEV energy level. They then emerge to strike a gold target, which gives off the penetrating X rays used for treatment.

STANFORD MEDICAL SCHOOL ADDS TWO NEW ASSOCIATE PROFESSORS TO FACULTY

The Stanford University School of Medicine has added two new associate professors to its Psychiatry Department faculty.

They are Dr. William C. Dement and Dr. Herbert Leiderman. Dr. Dement, whose appointment begins Dec. 1, has done extensive research on the functioning of the mind during sleep and dreaming. He is now associated with the Department of Psychiatry, Mount Sinai Hospital, New York.

Dr. Leiderman's appointment becomes effective June 1, 1963. He currently is an associate in psychiatry at Harvard Medical School and a career investigator for the U. S. Public Health Service. Dr. Leiderman has carried out clinical and laboratory investigations on sensory deprivation.

FOR RELEASE: At 10:30 a.m. (P.S.T.), Thursday, Nov. 1, 1962.

NOTE TO EDITORS: The following is a joint announcement from the Palo Alto (Calif.) Veterans Administration Hospital and the Stanford University School of Medicine.

PHOTOS AVAILABLE ON REQUEST.

BLOCKED CORONARY ARTERY OPENED IN RARE OPERATION

A team of Stanford University surgeons, working at the Veterans Administration Hospital in Palo Alto, Calif., has successfully cleaned out a completely blocked coronary artery which crippled a 47-year-old man.

The patient, who formerly suffered severe heart pain following the slightest physical exertion or emotional upset, is now ready to return to work as a laborer. Special X rays taken before and after the operation six months ago show the once entirely closed artery now carries blood to the heart muscle.

During the past five years a small number of operations on the coronary arteries have been performed by cutting directly through the wall of the vessel. But the high mortality rate has discouraged surgeons from continuing to use that method. The difficulty of operating on a beating heart, and the tendency for more clogging material to form at the incision, were key factors in the lack of success.

The Stanford surgeons used a new method in which the heart is stopped and repair done without cutting the coronary artery. The material clogging the blood vessel was removed by making an incision in the aorta, the large blood vessel which carries fresh blood to the body, and working down the coronary artery from its opening off the aorta.

- more -

Such an operation can be expected to be successful in only a small number of patients at the present time, according to Dr. John E. Connolly, who headed the surgical team. However, he believes this type of surgery will be more widely applied in the next few years. "It gives hope of helping many patients who currently die from coronary artery disease," he said.

A large percentage of deaths due to heart disease is caused by blocks in coronary arteries. Roughly a quarter of these blocks are localized enough to be removed surgically.

In some cases the patient may not die even though a coronary artery is blocked, because blood reaches the heart muscle by collateral circulation from other blood vessels. But the severe pain often seriously handicaps the patient, and there is always danger a fatal heart attack will occur.

Dr. Connolly, assistant professor of surgery at Stanford University School of Medicine and a consultant surgeon for the VA, directed a team of eight men who performed the operation. Dr. Frederic Eldridge, chief of medicine at the Palo Alto Veterans Administration Hospital and an associate professor of medicine at Stanford, directed the detailed diagnostic studies which preceded surgery.

Dr. Eldridge said that before the operation the patient, William Davis of Hanford, Calif., was incapacitated by pain. He was unable to shave himself, for instance, because the slight activity brought on such severe angina.

Davis' heart was stopped for three hours during surgery, and he was kept alive by a heart-lung machine. His body was also cooled to 59°F. to slow down bodily processes.

The surgeons found that Davis' right coronary artery was completely closed by stiff fibrous material containing calcium. At first they could not even locate the opening of the artery off the aorta. During the operation they also repaired the aortic valve leading from the heart, because the valve did not close entirely.

Davis has had no heart pain since the operation on April 25. His physicians believe that he will now be able to lead a completely normal life. Before the operation the block was located by a relatively new X-ray technique of injecting dye into the heart while moving pictures were made. Similar X rays made five months after surgery showed the artery is now open and of normal size.

Only one other successful coronary operation using a heart-lung machine has been reported in the medical literature. That was by a team in Paris, France. However, in that case as in all the other previous ones, the coronary arteries were not studied by X-ray techniques before or after surgery to demonstrate the arteries were successfully treated.

(Mailed Nov. 1, 1962) ####

BEFORE OPERATION

AFTER OPERATION

FOR RELEASE AFTER 10:30 A.M. (P.S.T.) THURSDAY, NOV. 1, 1962

X rays taken before and after coronary artery operation by Stanford surgeons at Palo Alto (Calif.) Veterans Administration Hospital show effectiveness of surgery. Left hand picture was taken before operation, and arrow 1 shows right coronary artery is not filling with blood. In right hand picture, taken five months after surgery, right coronary shows clearly. Arrow 2 in both pictures shows normal left coronary artery. (See accompanying story for details.)

STANFORD PROFESSOR NAMED PRESIDENT-ELECT OF NATIONAL SPEECH AND HEARING GROUP

New president-elect of the American Speech and Hearing Association is Dr. Hayes A. Newby, professor and associate director of the Division of Speech Pathology and Audiology of Stanford University School of Medicine.

He succeeds the current president, Dr. Jack Matthews, head of the Department of Speech, University of Pittsburgh, next January 1 and will therefore be president in the fall of 1964 at the time of the first annual convention ever to be held by the association in San Francisco.

Until the end of 1963 Dr. Newby is president of the American Boards of Examiners in Speech Pathology and Audiology, a branch of ASHA.

Dr. Newby received his B.A. at Ohio Wesleyan University in 1935, his M.A. and Ph.D. at the State University of Iowa in 1939 and 1947 respectively.

The national headquarters of the American Speech and Hearing Association is located in Washington, D.C. It is an organization of approximately 10,000 individuals working in the fields of speech and hearing. One of the primary functions of the ASHA, the only professional association in these fields, is to accredit persons for clinical competence.

MONTEREY COUNTY HEART ASSOCIATION CONTRIBUTES $8,000 RESEARCH TOOL

A valuable research tool, provided with funds from the Monterey County Heart Association, was installed in the Surgical Laboratories of Dr. Norman Shumway and Dr. Eugene Dong at Stanford Medical Center this week.

The $8,000 instrument is an electronic multi-channel recorder which will monitor several different readings simultaneously. It will be used to study the functional effects of whole heart transplantation in experimental animals. The Association's gift included a large contribution from an anonymous donor.

Seven members of the Board of Directors of the Heart Association visited Stanford to see the machine in operation. The members were David N. Gill of Pacific Grove, president; Dr. Donald Taugher of Monterey, immediate past president; Dr. Mast Wolfson of Monterey, research chairman; Dr. Arthur L. Wessels of Salinas, vice president; and Jack Patton, Mrs. Anthony Brazil and Harry L. Noland of Salinas.

Dr. Dong, the son of Dr. and Mrs. Eugene E. Dong, 1235 Garner Avenue, Salinas, is a graduate of Salinas Union High School and attended Hartnell College. He is now working in the Department of Surgery, Stanford University School of Medicine, as an Advanced Research Fellow of the American Heart Association.

The recorder can take simultaneous measurements on six different channels. It monitors such indicators of physical condition as blood pressure, temperature, electrical waves in the heart or brain, and oxygen and carbon dioxide content of the blood.

The animals to be studied have had their hearts removed surgically and then stitched back in place. The experiments are aimed at finding out whether transplanted hearts function normally over long periods of time. Some day, surgical transplantation of hearts will be available as a method for treating heart disease in human patients.

FOR IMMEDIATE RELEASE (For information contact: Pat Black, DAvenport 1-2300, ext. 5311)

MAISIE might be any of several million dogs who have just had a litter of pups. She is, however, different than any other "mother" in history. Sixteen months ago her heart was completely removed and stitched back into place. It was without circulation for 77 minutes while the heart-lung machine took its place. The operation was performed by Dr. Edward J. Hurley, one of a team of heart surgeons at the Stanford School of Medicine. This technique may be the first step toward operations in which a patient's heart is taken out of his body in order to correct serious heart defects and then replaced. The operation may eventually help a great number of the 15,000 blue babies born each year in this country with inoperable heart conditions. Maisie's operation was so successful that she had a normal electrocardiogram both five months after the operation and on the day before her seven puppies were born March 18 in Stanford's animal quarters. Her heart was apparently not affected by the extra stress placed upon it while she was delivering her large family.

NOTICE TO EDITORS:

One of the few lasers in the world being developed for treatment of eye conditions will be demonstrated at Stanford Medical Center Monday, April 1. A laser is an electronic device which produces a light beam thousands of times more intense than sunlight. While there are many potential applications for lasers in electronics and communications, they are just being developed for medical uses.

You are invited to send a reporter and/or photographer to the news conference. A story outlining the uses of lasers for eye surgery will be distributed at that time.

The news conference will be held in the Eye Clinic classroom of Stanford Medical Center beginning at 10:30 a.m. Your representative may come to the main information desk in the hospital lobby to get instructions for reaching the classroom.

Participating will be Dr. Milton Flocks and Dr. H. Christian Zweng, the ophthalmologists who use the laser and another device, the Zeiss photo-coagulator, for treating eye diseases; and Dr. Arthur L. Schawlow, Stanford professor of physics who was co-discoverer of the laser principle.

STANFORD RESEARCHERS PIONEER IN JOB REHABILITATION STUDY

A truck driver is in an accident which leaves him paralyzed from the waist down. A waitress develops glaucoma and can no longer see clearly enough to move in and out among tables.

How will they find suitable jobs in view of the physical and psychological effects of their disabilities? They represent just two examples of permanently disabled individuals who need to find new ways of earning their living.

This complex problem is being explored at the Stanford University School of Medicine by a research team representing medicine, psychology, industrial engineering and human factors engineering.

It is the only project in the country that uses scientific instruments to measure the extent to which the disabled are able to use various parts of their bodies.

Purpose of the research project, headed by Dr. G. Peter Paulhe, a research associate in rehabilitation medicine at the medical school, is to develop techniques of work-capacity assessment for the disabled. The assessment methods cover most of the significant aspects of work behavior and will be modified for use in rehabilitation centers throughout the country.

The team has built a small but complete "manufacturing plant." Various jobs around the plant are set up for patients to do. The motions of each job are scientifically classified. By having a patient work at a few jobs for several days, the team is able to determine which motions he can or cannot perform and the speed with which they are done.

- more -

For example, five parts bins containing screws, nuts, and clamps are set before the subject. Following a period of instruction, he is required to assemble these parts to make a finished cable clamp. The boxes are wired to recording instruments in an adjoining room which keep track of the time it takes a subject to complete each separate part of the total assembly.

A Grass Electroencephalograph recording device registers the patient's motion times. Fumbles, mistakes in sequence, work rhythm, and delays are permanently recorded for further study. Differences in the "expected times" and the "observed times" reflect the effects of the disability on the motions involved, with some motions being more adversely affected than others.

The instrumentation also permits the team to arrive at an estimate of the patient's fatigue throughout the day, and to differentiate between true physiological fatigue and other effects such as boredom or monotony. For certain types of impairments, the ability to make this distinction is a critical factor in recommending vocational training or job placement.

Another problem the team is studying is the individual's ability to adapt to variations in supervision, and to withstand the common stresses which arise on the job.

Following a carefully prepared script, the work supervisor imposes a regime of controlled pressure for performance, building from simple suggestions to stern demands and personal criticism. The patient's verbal responses are tape recorded and examined for any inappropriate reactions. Changes in breathing pattern, sweating, blanching and "nervousness" are noted by the supervisor. Signs of disorganization are sought in the recordings of the motion times. The stress testing is followed by an interview in which the procedure is explained to the patient and he is questioned about his reactions.

The study was begun a year and a half ago. Until the present, numerous man-hours have gone into processing the data but a recent grant of $50,000 from the Office of Vocational Rehabilitation of the U.S. Department of Health, Education, and Welfare will make it possible to use new recording equipment and permit the data to be processed by Stanford's giant 7090 computer.

In addition to Dr. Paulhe, Stanford members of the team participating in the research project are Dr. David A. Thompson, assistant professor of industrial engineering; William Dauterman, chief, Vocational Rehabilitation Services; Wallace McDonald, laboratory supervisor; Dr. Jose Montero, assistant professor of medicine; Bradley Efron, Statistics Department; and Mark Draper, research assistant. Dr. James Bliss and Ken Gardner, research engineers at Stanford Research Institute, Menlo Park, complete the research group.

NATIONWIDE STUDY TO DETERMINE SIDE EFFECTS OF ANESTHETIC

A nationwide investigation is under way into the possible dangerous effects of the widely used anesthetic halothane, which are of growing concern to the medical profession, Dr. John P. Bunker of Stanford University School of Medicine announced today.

Concern that halothane (marketed under the name "Fluothane") may harm the liver and sometimes cause death is based upon recent reports of liver damage following use of this agent. Two such reports appear in the current issue of the New England Journal of Medicine. Dr. Bunker, professor and executive head of the Department of Anesthesia at Stanford, was co-author of one of the articles.

Ten deaths have been reported so far. While this number is small compared with the number of patients who have had the drug during surgery -- an estimated six million Americans -- Dr. Bunker said that for every case reported many others may have gone unreported.

There is no evidence to date, however, to indicate whether halothane caused the deaths or whether other factors were to blame.

Nearly a dozen medical centers across the country are already signed up for the study. It will be directed by the Committee on Anesthesia of the National Research Council. Dr. Bunker is committee chairman. Other members are Dr. S. H. Ngai, associate professor of anesthesia at Columbia University, and Dr. Leroy D. Vandam, professor of anesthesia at Harvard University.

Data collected under carefully controlled conditions will be assembled at Stanford. Information will be summarized and analyzed with computers in the University's Computation Center.

- more -

"The importance of this kind of approach in studying the effects of drugs," Dr. Bunker said, "has become increasingly apparent to the medical profession and the public with the enormous number of new drugs and the appearance of unsuspected side effects from the use of such agents as thalidomide, the oral contraceptives and the polio vaccines."

Plans call for between 50,000 and 75,000 patients to be involved over 1½ to 2 years. Half will be given halothane, half another commonly used drug. All will be screened for possible liver damage by a sensitive laboratory test. If there is any indication of possible damage, further detailed tests will be ordered.

"If the incidence of liver death should turn out to be the same for halothane and non-halothane cases, presumably one need look no further," Dr. Bunker wrote in the medical journal. This would mean the anesthetic was no more harmful than other accepted drugs available.

But if significant differences in death rate due to liver damage show up, other factors will have to be investigated. Many other drugs, some often given in the course of hospitalization, may be implicated. Infectious hepatitis, a serious liver disease caused by a virus, may also be the cause of death and might occur coincidentally with use of halothane.

Half of all patients receiving general anesthesia now receive halothane, according to one estimate. It is regarded as a very useful anesthetic because of its effectiveness and because it will not explode. Older anesthetic gases had caused operating room explosions. Halothane has been in use since 1956.

Dr. Bunker said that the possibility of liver damage was not enough of a hazard to justify halting the use of the anesthetic until completion of the studies. But should a cause-and-effect relationship be established, physicians will probably cease giving halothane to patients with histories of liver disease.

Autopsies performed on patients who died from liver disease after receiving the drug showed the cells of the organ were severely damaged or dead. The liver stores and produces many chemicals necessary for life.

Other medical centers already enlisted in the program include the University of California at Los Angeles; Columbia-Presbyterian Medical Center, New York; Duke University; Hartford (Conn.) Hospital; Harvard University; University of Iowa; the Mayo Foundation, Rochester, Minn.; University of Miami (Fla.); University of Michigan; and University of Pennsylvania.

The study is already under way at Columbia-Presbyterian Medical Center and will begin at several others within the next few weeks.

HIGHEST ENDOCRINOLOGY AWARD GOES TO STANFORD PROFESSOR

The Sir Henry Dale Medal, the highest honor in endocrinology, will be presented to Philip E. Smith of Stanford University School of Medicine in May. Dr. Smith, Professor Emeritus from the Columbia University College of Physicians and Surgeons, has been a research associate in anatomy at Stanford since 1956.

The first American to be so honored, Dr. Smith is being given the award "in recognition of his outstanding and meritorious accomplishments as an investigator in the field of basic and clinical endocrinology."

Among the investigators on the function of the pituitary gland two names stand out, that of Harvey Cushing, pioneer American neurosurgeon, and Philip E. Smith, an experimental anatomist.

Dr. Smith demonstrated conclusively that the gonads, the thyroid and adrenal glands cannot develop or function without the pituitary gland, which is located at the base of the brain.

He did this by perfecting a surgical technique for removing the pituitary gland from animals without injuring their brains. Once the pituitary was removed the three glands wasted away. By injecting the pituitary into these animals, he found that these glands could be restored to their normal functions.

- more -

In recognition of his work on the pituitary gland, Professor Smith was elected to the National Academy of Sciences and was made a Chevalier of the French Legion of Honor.

Professor A. S. Parkes, one of the most widely known authorities on the reproductive system, will come from Cambridge University, England, to make the award at a dinner to be held at the Pioneer Inn, Woodside, Thursday evening, May 9, 1963.

The president of the Society for Endocrinology of Great Britain, Professor E. C. Amoroso, will be on hand for the presentation. Dr. Amoroso, one of the world's leading authorities on the structure and function of the placenta, is currently on leave from the Royal Veterinary College in London to teach for one year at Washington University in St. Louis.

Established by the Society for Endocrinology in 1959, the award has been received by such well-known scientists as Charles Best of Canada, an eminent physiologist and co-discoverer of insulin; Bernardo A. Houssay of Argentina; Professor Sir Charles Dodds of England, who was knighted because of his work; and Professor A. Butenandt of Germany. Two of the recipients, Houssay and Butenandt, are Nobel prize winners.

FOR RELEASE TO A.M. NEWSPAPERS OF SATURDAY, April 27, 1963

An unusual library -- the result of a professional lifetime of work by the dean of pediatricians on the West Coast -- has found a new home at Stanford Medical Center.

It is the collection of Dr. Harold K. Faber, head of the Department of Pediatrics at Stanford University School of Medicine for 26 years before his retirement in 1949.

A unique part of the collection is a reprint, abstract and cross-index file which covers the expanding field of pediatrics. With this file, which contains over 50,000 items, needed information is available faster than from any printed source.

The new Faber Library in the Department of Pediatrics at Stanford was the setting for a reception yesterday honoring Dr. and Mrs. Faber. Guests included many former students and house officers of Dr. Faber's, who sponsored a dinner at the Menlo Circus Club following the reception.

The library is on the third floor of the Boswell Building in Stanford Medical Center. Mahogany paneling lines the walls. On one wall hangs a portrait of Dr. Faber, painted by Alfred Jonniaux of San Francisco. In addition to the cross-index file, the library also houses specialty journals and texts.

Dean Robert H. Alway of the medical school said that "the library continues the scholarly and scientific contributions of Dr. Faber to child health and to development of many fledgling pediatricians who seek to follow in his footsteps." Dr. Alway also praised it for providing "a retrospective view of many pediatric subjects not adequately encompassed in any available printed material."

Dr. Faber is internationally known for his polio research as well as for his teaching and clinical skills. He is a former president of the American Pediatric Society, and received the Society's Howland Medal and Award in 1956 for his extensive contributions to the profession.

STANFORD SPONSORS REHABILITATION INSTITUTE

Up-to-date techniques for teaching principles of rehabilitation to medical students will be outlined during the Third Institute on Teaching of Rehabilitation Medicine at Stanford April 17 - 20.

The first such institute to be held in the West, it is being sponsored by the Stanford University School of Medicine in cooperation with the Vocational Rehabilitation Administration of the U.S. Department of Health, Education, and Welfare.

More than 75 representatives from medical schools having teaching programs in rehabilitation medicine have been invited to attend the four-day meeting.

Purpose of the periodic institutes is to evaluate new methods of teaching students to recognize and manage problems caused by crippling diseases or accidents and their impact on the persons involved.

STANFORD MEDICAL STUDENT WINS $150 RESEARCH AWARD

Bryan Brewer, Jr., won the $150 Palo Alto Medical Clinic prize for the outstanding paper presented at the third Stanford Student Medical Conference, it was announced today.

Brewer is a third-year student at the Stanford University School of Medicine. His home is in Casper, Wyo.

He studied the effect of nitrogen mustard (a drug used in treating acute leukemia) on mice cells grown in glass flasks. Brewer found no effect on DNA (deoxyribonucleic acid) between the treated cells and samples which had not been treated, even though the drug had a marked effect on the growth of the cells. DNA is associated with the transmission of hereditary characteristics and with cell division.

Brewer's paper was one of six presented by students at the day-long conference held April 6. The annual meetings are sponsored jointly by the Stanford Medical Student and Stanford Medical Alumni Associations.

Other students presenting papers at the conference were Robert P. Erickson, a third-year student from Berkeley, whose research concerned the heredity of blood proteins in mice; Harvey L. Ozer, a third-year student from Dorchester, Mass., who localized antigens (antibody-producing chemicals) in certain cell membranes of the livers of mice; and Carl D. Petersen, a third-year student who lives in Palo Alto, who discussed the causes of mongolism in the children of young mothers.

- more -

Ward Trueblood, a senior from Indianola, Iowa, reported how the movement of the stomach affects the production of a hormone involved in gastric acid secretion. Irving Weissman, a third-year student from Great Falls, Mont., described the differences in the acceptance or rejection of skin grafts between male and female mice.

The presentation of a clinical case was also part of the day's program. John Gribble of San Jose presented the findings from the autopsy of a patient with an unusual form of diabetes. John D. Earle of Sacramento discussed the patient's X rays. Both Gribble and Earle are third-year students.

Featured speaker for the day was Dr. William Dock of the Downstate Medical Center of the State University of N.Y. He addressed the students on ballistocardiography, a technique for measuring the force of the heart beat by measuring the movement of the body.

EDITORS: Parents' names and home addresses follow:

Bryan Brewer, Jr., Mr. and Mrs. Hollis B. Brewer, 1357 East 2nd, Casper, Wyo.

John D. Earle, Mr. and Mrs. Clarence M. Earle, 3313 Edison, Sacramento

Robert P. Erickson, Dr. and Mrs. Harold M. Erickson, 1314 Grizzly Peak Blvd., Berkeley

John Gribble, Mr. and Mrs. James W. Gribble, 3629 Union Ave., San Jose

Harvey L. Ozer, Mr. and Mrs. Samuel Ozer, 11 Ashton St., Dorchester, Mass.

Carl Petersen, 3109 Maddux Dr., Palo Alto

Ward Trueblood, Mr. and Mrs. C. A. Trueblood, 906 North C St., Indianola, Iowa

Irving Weissman, Mr. and Mrs. Maurice Weissman, 3027 4th Ave. North, Great Falls, Mont.

IMPORTANT CORRECTION -- Notice to editors and writers: Due to an unintentional oversight, the story mailed yesterday regarding the laser being developed for treatment of eye conditions did not give proper credit to the developing organization or the individuals involved. In the following version, amended or new paragraphs are underlined to show where corrections have been made.

LASER BEING DEVELOPED FOR TREATMENT OF EYE DISEASES

An electronic device which produces a light beam thousands of times more intense than sunlight is being developed at the Palo Alto Medical Research Foundation to correct serious eye conditions.

The instrument is a laser, which amplifies light waves the way other electronic equipment amplifies radio waves. It is one of only a few lasers in the world used for such purposes.

Light coagulation therapy, which involves the use of intense beams generated by the laser and another machine, will be explained and demonstrated to two dozen ophthalmologists attending a postgraduate course at Stanford next week (APRIL 11-12). The second device is a Zeiss photo-coagulator, which utilizes light from a xenon gas tube.

Faculty for the course will be Dr. Milton Flocks and Dr. H. Christian Zweng of the Division of Ophthalmology at Stanford University School of Medicine, and Stanford Professor of Physics Arthur L. Schawlow.

Prof. Schawlow was a co-discoverer of the laser principle. Dr. Flocks is clinical associate professor and Dr. Zweng clinical instructor in the medical school.

The laser to be demonstrated is being developed under a National Institutes of Health grant to the Palo Alto Medical Research Foundation. Chief investigator is Dr. Narinder Kapany, who has directed the research and development for the laser at Optics Technology in Belmont, Calif. Dr. Kapany is president of the firm.

- more -

The instrument is the collaborative effort of Dr. Kapany, Dr. Flocks, Dr. Zweng, and two engineers at Optics Technology, Norman Peppers and Norman Silbertrust. Dr. Flocks and Dr. Zweng have conducted experimental trials on animals with the laser in the Stanford Division of Ophthalmology.

It is only in the last decade that light beams have been put to use for treating eye conditions. The photo-coagulator was developed in 1954. The first experimental laser for use by ophthalmologists was made in 1962.

One condition the light beam is particularly effective in preventing is retinal detachment, in which the light-sensitive retina comes loose in the eye. Thousands of Americans develop retinal detachment each year.

If discovered early, the retina can be "spot welded" back in place by the light beam. A small scar develops where the beam has burned the tissue behind the retina, holding the retina in place.

The burning beams can also be used to scar and essentially destroy certain blood vessel tumors in the eye, to make a new pupil in a blocked iris or one that is out of position following surgery, or to destroy tumors on the surface of the eye.

The laser is regarded as an important improvement in light coagulation for three reasons. First, a much briefer exposure is required and there is no danger a patient will flinch or turn his eye; the beam need only be on for 1/1000th of a second. Second, treatment is so fast it doesn't hurt, and no anesthetic is required. Third, the equipment is more compact and thus much easier to use.

With both the photo-coagulator and the laser, the beam must be directed against a pigmented section of the eye, since the beam passes through transparent material such as the lens or the retina.

The postgraduate course is one of the first to be given on light coagulation anywhere in the world outside of Germany, where the Zeiss photo-coagulator was developed. It is the first ever to be given on laser coagulation of the eye.

PALO ALTO MEDICAL STAFF ESTABLISHES MEMORIAL PROFESSORSHIP

The first Charles D. Armstrong Memorial Professorship in the Stanford University School of Medicine will be occupied by Dr. Eugene A. Stead of Duke University.

This annual visiting professorship has been established by the Palo Alto Medical Staff to honor the late Dr. Charles D. Armstrong, co-founder of the Menlo Medical Clinic, and chief of staff of the Palo Alto Hospital in 1956-57.

Dr. Stead will be in residence at the Stanford Medical Center from April 8 to 12. A professor of medicine at the Duke University School of Medicine and physician-in-chief at Duke Hospital, he is an authority on the dynamic changes occurring in the heart and circulation during heart failure.

While at Stanford Dr. Stead will be acting professor in the Department of Medicine and will take over many of the routine teaching duties. In addition, he will conduct ward rounds, work with medical students and house staff, and be available for staff consultations.

He will give a lecture Wednesday, April 10, at 8 p.m. in room M106 at the Medical Center. It is open to all physicians in the community.

Dr. Stead was chosen as the first visiting professor by a committee composed of Dr. Walter L. Arons and Dr. Marcus Krupp of the Palo Alto Medical Staff, and Dr. Halsted Holman, executive head of the medical school's Department of Medicine.

- more -

The Charles D. Armstrong Memorial Professorship was established by the internists in the community to support the teaching program of Stanford's Department of Medicine. At the time of his death at the age of 44 last year, Dr. Armstrong was an assistant clinical professor of medicine at Stanford. In addition, he was a private practitioner and a research associate in the cancer research division of the Palo Alto Medical Research Foundation.

Funds for the Professorship are being furnished by individual contributions from members of the Division of Medicine of the Palo Alto Medical Staff plus a contribution from the Staff's general funds.

FOR RELEASE FRIDAY, APRIL 5, 1963

STANFORD PHYSICIAN CITED FOR OUTSTANDING METABOLIC RESEARCH

"A brilliant student of metabolic disturbances in man," Dr. John A. Luetscher, professor of medicine at the Stanford University School of Medicine, is this year's recipient of the John Phillips Memorial Award.

He received the award last night (April 4) from the American College of Physicians because "he has stimulated and extended our knowledge of metabolic states," according to the citation.

The Phillips Award, established in 1929, is given annually for distinguished contributions in internal medicine.

Dr. Phillips, in whose memory the award was established, died during the disastrous Cleveland Clinic fire in May 1929 while trying to rescue others from the building. At the time he was a member of the Board of Regents of the American College of Physicians.

Dr. Luetscher was cited for his pioneer work "in demonstrating and in isolating a sodium retaining hormone in the urine of patients with edema." Commonly known as dropsy, edema is an excessive accumulation of fluid in the tissues.

While seeking the causes of dropsy, Dr. Luetscher was "the first to show that a hormonal factor, later called aldosterone, was involved in various edematous conditions."

He was presented the award at the convocation ceremonies, a highlight of the 44th Annual Session of the American College of Physicians in Denver.

Nobel laureate Dr. W. F. Libby, professor of chemistry at the University of California at Los Angeles, was the major speaker at the convocation.

For Release to A.M. Newspapers of Tuesday, June 4, 1963. (Release time set by Richard King Mellon Charitable Trusts.)

STANFORD MEDICAL SCHOOL WILL RECEIVE $250,000 FOR FACULTY SALARIES

The Stanford University School of Medicine will receive $250,000 from the Richard King Mellon Charitable Trusts to augment the salaries of faculty members engaged in medical teaching, it was announced today in Pittsburgh, Pa.

Stanford is one of 23 private medical schools in the country which will receive similar grants. All told, the Mellon Trusts will distribute $5,750,000 "to help meet the most pressing need medical schools face today."

"There is an especially critical need for increased support for younger faculty members working in the basic sciences, which constitute such an important foundation in medical education," the Mellon Board of Trustees stated.

"This timely grant," Dean Robert H. Alway of Stanford's medical school said, "will enable us to recruit and retain faculty we require, particularly in the basic sciences most in need of promising young scientist-teachers."

Stanford is one of only two schools west of St. Louis receiving Mellon grants. The other is at the University of Southern California. The grants will be made in $50,000 annual installments over the next five years.

The 23 schools were chosen following a study by Dr. Willard C. Rappleye, retired dean of the College of Physicians and Surgeons at Columbia University, and Dr. Fordyce B. St. John, retired professor of clinical surgery at the Columbia-Presbyterian Medical Center in New York City. Selections were based on need, demonstrated excellence and geographical distribution.

FOR FURTHER INFORMATION CONTACT: Samuel Moffat (DA 1-5310)

FOR RELEASE: Friday noon (PDT), May 24, 1963. (Release is timed to follow Dr. Lederberg's talk at the Stanford Medical Alumni-Faculty Reunion.)

NOTE TO EDITORS: Reprints of the Nature article are available on request.

CONTROL OF DEVELOPMENT LIKELY TO PRECEDE APPLICATION OF EUGENICS TO HUMANS

Control of development, or "euphenics," rather than the control of heredity, eugenics, is likely to provide the first approach for altering the physical characteristics of human beings, Dr. Joshua Lederberg of Stanford University said today.

Furthermore, he said, the pace of current research in fundamental biology suggests that methods of changing human development will be available much sooner than scientists had previously expected.

Dr. Lederberg spoke at the 1963 Stanford Medical Alumni-Faculty Reunion on campus today. He recently published a paper on the same topic in the British scientific journal Nature.

A co-winner of the 1958 Nobel Prize in physiology and medicine, he is professor and executive head of the Department of Genetics at Stanford University School of Medicine.

Dr. Lederberg has coined the word "euphenics" to show the difference between what he is talking about and the approach of eugenics. Eugenics aims at altering the genetic makeup of individuals by such methods as selective breeding. The new word comes from a term in genetics, the phenotype, which means the visible organism that develops from the genetic material, the genotype.

- more -

Genetic changes would take much longer to put into widespread use, Dr. Lederberg believes. Not only is the knowledge of human genetics still very limited, there are also social constraints and long periods of time between generations. All of these will delay application of eugenic principles.

In contrast, some techniques for euphenics are nearly ready. Transplantation of life-extending organs has begun with the kidney and the methods may be ready soon to allow other organs to be grafted.

In another part of the body, "it would be incredible if we did not have the basis of developmental engineering technique, for example, to regulate the size of the human brain by prenatal or early postnatal intervention."

Dr. Lederberg bases his conclusions on recent accomplishments and anticipated discoveries in molecular biology. This is the study of living things at the molecular level, where life processes are directed and regulated.

It includes the chemical makeup of genes and how small changes in them alter the organism produced. It also deals with the manufacture of proteins, the chemicals which make up most of the structure of living things and which direct life processes such as the development of an egg into an animal, subsequent growth to adulthood, the recording of information in the brain, and many more.

Molecular biology should have broad applications in embryology, learning, immunity (to diseases, and to foreign tissues which might provide new organs in place of diseased ones), and to the understanding of cancer and aging.

"The emphasis on eugenics as the point of application of molecular biology overlooks the most immediate prospects for the understanding and then control of human development...development is the translation of the genetic instructions of the egg...to direct the unfolding of its substance to form the adult organism in all its aspects," Dr. Lederberg wrote.

"Until now, major problems of human development -- embryology, learning, immunity, uncontrolled cellular growth such as cancer, and aging -- could be approached only at the most superficial level. They are about to be transformed in the sense that genetics has been," as a study of small chemical steps.

"The present intensity of effort suggests a span of from five to no more than 20 years" for development of a systematic understanding in these areas.

Scientists must begin thinking about the implications of research results which are just around the corner, Dr. Lederberg believes. Even though "the risks of scientific prophecy are well known," some concerted forethought is needed now to plan how to deal with the possibilities.

YALE SURGEON NAMED TO HEAD DEPARTMENT AT STANFORD MEDICAL SCHOOL

Dr. Robert A. Chase of Yale University School of Medicine will become executive head of the Department of Surgery at Stanford University School of Medicine August 1.

Now chief of the Section of Plastic and Reconstructive Surgery at Yale, he was appointed by the Stanford Board of Trustees at its May meeting. He succeeds Dr. Harry A. Oberhelman, Jr., acting executive for the last year.

"In addition to his clinical and investigative skills, his excellence as a teacher is noteworthy," Dean Robert H. Alway of Stanford's medical school said. The Yale medical graduates of 1962 gave him the Francis Gilman Blake Award as their outstanding teacher of medical science.

Dr. Chase's selection culminates an intensive two-year search for a departmental executive able to lead surgical education and training in Stanford's new five-year curriculum. The curriculum went into effect in 1959, the same year the medical school moved from San Francisco to Stanford.

(Dr. Chase will be attending the Stanford Medical Alumni-Faculty Reunion at Stanford Friday (MAY 24) to meet alumni for the first time.)

The new executive is 40 years old. He earned a B.S. degree from the University of New Hampshire in 1945 and received his M.D. from Yale two years later. At Yale he was elected to Alpha Omega Alpha, the medical honor society. He joined the Yale faculty as an assistant professor of surgery in 1959 and was subsequently promoted to associate professor.

- more -

He received his postgraduate training in general surgery at Yale New Haven Medical Center and in plastic and reconstructive surgery at the University of Pittsburgh.

As a surgeon in the U.S. Army he was chief of surgery at the Ft. Monmouth (N.J.) Army Hospital in 1950-51 and at the Army Hospital in Leghorn, Italy, 1954-57. He was chief of the hand surgery service at Valley Forge (Pa.) Army Hospital in 1951-52.

Dr. Chase's research has been in two principal areas. One relates to patients with cleft palates and other palate and pharynx disorders. The pharynx is the tube running behind the nose, throat and voice box.

These studies, which include analysis of breathing, X-ray movie techniques, and other methods, are aimed at improving treatment for patients with these disorders.

The other area involves laboratory investigations of tendon healing and regrowth of nerves, which are important problems in reconstructive surgery.

Dr. Chase is married and the father of three children.

MEDICAL ALUMNI TO MEET AT STANFORD REUNION MAY 24

A Nobel Prize geneticist and two physicians will be the featured speakers for the Stanford Medical Alumni-Faculty reunion Friday, May 24.

This is the first time the reunion has been scheduled in the spring. It is now being held immediately before the Stanford Alumni Conferences May 25 to allow medical alumni to attend both meetings. Medical Alumni Day used to be held before the Stanford-California Big Game in November.

Major speakers for the reunion are Dr. Halsted R. Holman, Dr. David A. Hamburg and Dr. Joshua Lederberg. They head the Stanford Departments of Medicine, Psychiatry and Genetics respectively. They will speak in the morning at Memorial Auditorium.

Dr. Holman will discuss "The Survival of Tissue Grafts," Dr. Hamburg "Recent Research on Grief and Depression," and Dr. Lederberg "Medicine and the Future of People." Dr. Lederberg shared the 1958 Nobel Prize in physiology and medicine.

Another new feature of the reunion this year will be an afternoon of clinical sessions for the physicians, held at Stanford Medical Center. The three sessions will run concurrently; each will include lectures on five different topics.

Two sessions will deal with medical specialties. The third, sponsored by the Stanford Surgical Society, will cover surgical topics.

In the evening there will be an alumni-faculty dinner dance at the Menlo Circus Club in Atherton.

DEDICATION CEREMONY TO MARK OPENING OF CENTER FOR STUDY OF PREMATURE INFANTS

The first research center established by the National Institutes of Health for the study of premature infants will be dedicated at Stanford Medical Center Friday (MAY 17).

First patients will be admitted to the six-bassinet unit next week. It is the only center in California devoted exclusively to research into the problems of prematurity.

The purpose of the center is to provide a setting for intensive investigation of a small number of infants. Electronic equipment of the type developed for the man-in-space program will be used to continuously record information about the babies' bodily functions from their heartbeats to their metabolism.

Main speakers for the dedication will be Dr. Samuel Z. Levine, professor emeritus of pediatrics at Cornell University Medical College, and Dr. Robert A. Aldrich, director of the National Institute of Child Health and Human Development. Dr. Aldrich is the newest member of the National Institutes of Health in Bethesda, Md.

Workshop sessions dealing with problems of caring for newborn infants will be held for physicians and nurses during the afternoon.

Babies will be admitted to the center only on referral from physicians. Admission will depend upon the availability of beds and the particular needs of the center for infants of various weights and ages. It is expected most babies will come from within 50 miles of Stanford.

The $267,305 grant from the NIH for construction and the first year of operation covers full hospitalization expenses for patients. The NIH expects to support the center for a minimum of seven years, with an estimated investment of about 1½ million dollars.

Program director for the center is Dr. Sumner Yaffe, assistant professor of pediatrics. Investigators from many departments of the Stanford University School of Medicine will take part in patient care, research and teaching programs. The physicians hope their findings will lead to methods for reducing the high death rate among premature infants as well as the high incidence of mental retardation, nervous disorders and birth defects.

STANFORD RESEARCHERS TRACK DOWN GENES IN INFECTION-CAUSING BACTERIA

CLEVELAND -- What is the elusive element in some bacteria that make them capable of causing infection when many closely related bacteria are normal inhabitants of the human body and usually cause no harm?

Research being conducted at Stanford University School of Medicine by Dr. Robert Roantree, assistant professor of microbiology, and Dr. John Steward, instructor in basic medical sciences, may lead to the answer to this question.

Dr. Roantree disclosed the progress of this research in a paper presented last night (MAY 8) at the annual meeting of the American Society for Microbiology.

The two doctors have found that a mutation (a change in a gene) toward penicillin resistance, probably involving only a single gene, greatly reduces the ability of a strain of bacteria to cause death from infection.

The blood serum of most animals kills some bacteria because of the action of antibodies in conjunction with certain other serum proteins. The bacteria used in these experiments are resistant to this serum. However, the mutation which makes the bacteria less able to cause infection also makes them sensitive to the serum.

Drs. Roantree and Steward have been using a strain of bacteria which causes mouse typhoid fever and find that the mutant strain is 10,000 times less able to cause infection in the mouse than the parent strain.

A back mutation has been discovered which yields a strain of bacteria that is just like the parent and is again deadly for the mouse.

It is hoped that finding the structural and genetic differences existing between the original and mutant strains will lead to the discovery of one of the reasons for the disease-causing properties of the virulent strain and other bacteria of the typhoid fever group.

NEW NEUROLOGY FACILITY OPENS AT STANFORD MEDICAL CENTER

A new and greatly expanded diagnostic facility for comprehensive and up-to-date analysis of diseases of the nervous system has just been opened at Stanford Medical Center.

This facility will offer the community and referring physicians the possibility of much more detailed diagnostic evaluation of patients with epilepsy, Parkinsonism, cerebrovascular disorders (strokes), neuromuscular disease, multiple sclerosis, cerebral palsy, mental retardation and other neurologic diseases of infancy and childhood.

The unit is located on the third floor of the Palo Alto-Stanford Hospital and serves both hospitalized patients and outpatients visiting the Stanford Clinics.

The 2,900-square-foot unit cost $116,800 for construction and office equipment. This was paid for by Stanford University School of Medicine. The facility also includes $106,000 worth of scientific equipment which was paid for principally by grants from the National Institutes of Health.

The new facility will be operated in conjunction with two clinical neurological research facilities (one for premature infants and one for adult inpatients) recently awarded by the National Institutes of Health. Some new and very promising approaches to diagnosis and treatment of neurological disease are being explored in these research facilities.

- more -

Among the most important of the methods recently developed is one which analyzes the minute electrical signals generated within a particular sensory system in a small part of the brain (such as the part which responds to sound or to verbal signals). The system is sensitive enough to detect brain damage even in young children where ordinary examination shows no defect or the children are considered behavior problems or mentally retarded. In many such cases a specific and localized abnormality of electrical pattern or biochemical reaction has been found which drastically alters the course of treatment and offers a greater possibility of cure. Most of the work so far has been concentrated on youngsters whose ears and auditory nerves function properly but who can't make sense of what they hear or fail to develop normal speech. The difficulty has been traced to a damaged portion of the brain's auditory association area, where hearing sensations are compared with past experience and with other sensations such as sight.

In addition, the Stanford neurologic service has been designated as part of a National Institutes of Health-Veterans Administration Epilepsy Center. This includes a 47-bed ward at the Palo Alto V.A. Hospital and two free beds at Stanford Medical Center. Stanford faculty members care for patients at both institutions.

The facilities are under the direction of Dr. Frank Morrell, Stanford Professor of Medicine (Neurology) and head of the Division of Neurology and Electroencephalography Laboratories. The new unit will enable the Hospital to double its capacity for electroencephalographic (EEG) and electromyographic (EMG) examinations. EEG tests record brain waves, EMG tests record electrical signals in muscles.

AVALON FOUNDATION PROVIDES $50,000 FOR STANFORD MEDICAL SCHOOL SCHOLARSHIPS

The Avalon Foundation has given Stanford University School of Medicine a grant of $50,000 to be used for scholarships over the next three to five years, Dean Robert H. Alway announced today.

"This grant is particularly valuable in that it makes possible scholarships for first-year medical students," Dean Alway said.

"Until now money has not been available for first-year scholarships. As a result, some excellent students have not been able to enter Stanford, even though it was their first choice."

This is the third scholarship grant to Stanford from the Foundation. The medical school received $10,000 in 1961 and again in 1962.

The Avalon Foundation was established in 1940 by Mrs. Ailsa Mellon Bruce. Its headquarters are in New York City. In 1961-62 its grants for medical school scholarships came to $1,963,500.

The new grant will bring in an additional $16,666 for the unrestricted use of the University under the terms of the 1960 Ford Foundation 5-year incentive grant to Stanford. The Ford Foundation is providing $1 for every $3 raised from other private sources. Its grant sparked the current $100 million PACE (Plan of Action for a Challenging Era) campaign.

TOP CELLULAR CHEMIST NAMED TO STANFORD MEDICAL FACULTY

Dr. Robert L. Hunter of the University of Michigan, considered one of the nation's finest histochemists, will join the faculty of Stanford University School of Medicine Sept. 1.

He will be an associate professor of anatomy. His appointment rounds out the department's program in microscopic anatomy.

Histochemistry is the study of chemical substances in the body on a cellular level. Dr. Hunter is noted for developing new techniques for detecting enzymes, or natural chemical catalysts, in tissues.

He now holds a Career Development Award from the National Institutes of Health. These are given to the most promising younger investigators in the medical sciences.

At present Dr. Hunter is organizing an international conference on histochemistry to be held at the University of Recife in Brazil next month.

He received his bachelor's and master's degrees from Ohio Wesleyan University and his Ph.D. at Michigan. He has been on the Michigan faculty since 1953, and is now an associate professor of anatomy there.

NOTE TO EDITORS: Photo of Dr. Newby available on request.

AUTHORITY ON HEARING NAMED HEAD OF STANFORD MEDICAL SCHOOL DIVISION

Dr. Hayes A. Newby, nationally known expert on hearing, takes over as director of the Division of Speech Pathology and Audiology in Stanford University's School of Medicine Sept. 1.

He replaces Dr. Virgil A. Anderson, an authority on the voice and its disorders, who will continue on the faculty and devote most of his time to teaching and writing.

The new director is president-elect of the American Speech and Hearing Association and is serving his second year as president of ASHA's Board of Examiners in Speech Pathology and Audiology. He will be president of ASHA in the fall of 1964 at the time of the Association's annual convention. It is the first ASHA convention ever to be held in San Francisco.

Dr. Newby has been on the Stanford faculty since 1947. In addition to his teaching duties at Stanford, he was director of the San Francisco Hearing and Speech Center from 1948 to 1956 and is currently a consultant to that organization as well as the Veterans Administration and the California State Department of Health. He is a member of the training panel in speech pathology and audiology for the Vocational Rehabilitation Administration.

- more -

For the last six years Dr. Newby has been associated with the TV program Doctors News Conference. He has moderated the program for the past two years.

In 1958 he wrote Audiology, a textbook dealing with hearing and hearing disorders. The second edition of the book is being prepared for publication in the spring of 1964.

A graduate of Ohio Wesleyan University, Dr. Newby received his M.A. and Ph.D. from the State University of Iowa. He has taught at Louisiana Polytechnic Institute and the State University of Iowa, and has served as an officer in the U.S. Navy.

Dr. Anderson has been on the Stanford faculty for three decades. He was director of the Speech and Hearing Clinic of Stanford's Department of Speech and Drama from 1932 until 1957.

That year the Clinic became a division of the medical school and Dr. Anderson remained the director. Dr. Anderson is the author of one of the pioneer texts in his field, Training the Speaking Voice.

FOR RELEASE after 2 p.m. (P.D.T.) Tuesday, Aug. 20, 1963

NOTE TO EDITORS: Copies of this release will also be available at a press conference which Dr. Levinthal will take part in at the Cow Palace, beginning at 10:30 a.m. Aug. 20.

2-POUND INSTRUMENT DESIGNED TO DETECT POSSIBLE LIFE ON MARS

A small instrument weighing just over two pounds and capable of a wide range of biological experiments has been designed at Stanford Medical Center to investigate the possibility that life might exist on Mars.

Details of the device, known as a multivator, were outlined today at the Western Electronic Show and Convention (WESCON) at the San Francisco Cow Palace.

The multivator was developed under a grant from the National Aeronautics and Space Administration to the Instrumentation Research Laboratory of the Department of Genetics at Stanford. It is being considered for the first capsule mission planned for a landing on Mars.

Nobel Prize winner Dr. Joshua Lederberg, who heads the department, and his associate Dr. Elliott Levinthal spoke at a special WESCON session on extraterrestrial life. Dr. Lederberg discussed some of the broad problems involved in detecting life in space, and Dr. Levinthal explained how the multivator was designed to serve as a possible experimental device.

Physically, the instrument package is about the size of a milk carton. It is just under 10 inches long and about 2 3/4 inches in diameter. It weighs about 30 ounces at this stage of development, but may be miniaturized later.

- more -

Dr. Levinthal stressed that the device is a joint effort involving the contributions of many men, including members of the Mechanical Engineering Department at Stanford, and the Jet Propulsion Laboratories in Pasadena.

The instrument was designed specifically to accomodate a wide variety of experiments, so that it can be used by other investigators jointly with the Stanford group.

The purpose of the instrument is to analyze a dust sample for microscopic organisms, since these would be found in every pinch of dust or puff of wind. The dust will be collected from the planet's surface and blown into the reaction chambers within the multivator.

The dust will collect on a sticky coating on the chamber walls. A solvent, probably water, will be injected into the chambers where chemically reactive materials will already have been stored.

There are 15 chambers, three of which are blanks. The 12 working chambers will contain the reactive materials which will amplify certain steps in the metabolism, or chemical activity associated with life processes, of the microbes. Thus the presence of relatively few organisms can be detected. The blank chambers will serve as checks on the reaction to insure the reliability of the tests.

At present a test is being devised for a common enzyme (natural chemical catalyst) which is produced by all earthly organisms. The product of the enzyme reaction is a fluorescent material which can be electronically detected when a small light goes on inside the multivator. Information as to the progress of any reaction within each chamber can be telemetered back to earth.

The multivator could also measure growth of bacteria and be adapted to use radioactive tagging techniques. Solvents other than water, different solvents in each chamber, and measurements of conductivity, acidity and the like, could be worked into the design.

In outlining the problems of detecting signs of life elsewhere than on earth, Dr. Lederberg said that one could look for any one of the three stages in the evolution of life on Mars:

1. The development of complex organic (carbon) compounds which are typically associated with life but do not necessarily indicate that life exists.

2. The development of more complicated compounds which are reproduced and which contain genetic information that specifies what organisms will be like. Errors in this reproduction, together with natural selection, bring about evolution and the great variety of earthly life.

3. The evolution of mechanisms for thought, perception, and the accumulation of knowledge associated with intelligent communication.

The multivator has been designed to examine the possibility that the second stage has occurred. The presence of organic materials would indicate biological processes could have developed, but would not provide a precise indication that life existed.

Current experiments proposed for the instrument are based on the assumption that life on Mars would depend upon the same basic carbon chemistry that supports life on our planet. Should this prove not to be the case, further experiments would have to be designed to test for alternative forms of life.

In attempting to analyze Martian soil for traces of life, the scientists hope eventually to be able to tell whether Mars took the same general path as the earth in the chemical development of life, and how it diverged at any of the stages of evolution.

STANFORD PHYSICIAN'S BOOK COVERS ROLE OF KIDNEY IN HIGH BLOOD PRESSURE

Dr. Thomas A. Stamey of the Stanford University School of Medicine is the author of a new book about the latest methods of studying kidney conditions in man which lead to high blood pressure.

The book, entitled "Renovascular Hypertension," was recently published by The Williams & Wilkins Company of Baltimore, Md. (pp. 232, $14.50).

Dr. Stamey is associate professor of surgery and chief of the Division of Urology for the medical school. He is widely known for his work in developing a new test for telling when a kidney is responsible for high blood pressure.

Information gathered during the development and use of the test forms much of the material in the book. The technique depends upon obtaining separate urine samples from each kidney, in order to compare simultaneously a diseased organ with the other normal or less diseased kidney.

In his preface, Dr. Stamey notes: "This book is addressed to all physicians interested in the problem of hypertension; the general practitioner, the internist, the urologist, the vascular surgeon, and the diagnostic radiologist."

The introduction contains a description of certain basic concepts which are intended to help the physician understand the principles involved in the test "rather than accept some magical and arbitrary figures which indicate the presence or absence of disease."

PALO ALTO-STANFORD HOSPITAL CENTER ANNUAL OWNERS MEETING

The annual members' meeting of the Palo Alto-Stanford Hospital Corporation will be open to the public, its owners said today. The meeting will be Wednesday at 4:30 p.m. in Edwards Hall at Rickey's Hyatt House in Palo Alto.

Announcement of the decision was made by President J. E. Wallace Sterling for Stanford University and Mayor Dean R. Cresap for the City of Palo Alto. The Hospital is operated as a joint venture of City and University.

In the past, all business transacted at the annual owners' meeting had been previously acted upon by the City Council and only two city representatives needed to attend. This year, however, invitations have been sent to all councilmen, since the Hospital's Board of Directors wishes to make important presentations with which it feels all councilmen should be familiar.

Two major items for consideration by the owners will be the subject of open Board meetings and proposals concerning the organization of the Hospital.

Mayor Cresap will preside at the meeting.

FOR RELEASE SATURDAY, SEPTEMBER 14, 1963

(ADVANCE) STANFORD - Stanford University will receive a $500,000 grant from the Gustavus and Louise Pfeiffer Research Foundation to endow a teaching chair in the School of Medicine, the Foundation announced today in New York.

The Emma Pfeiffer Merner Professorship at Stanford is one of six to be set up by Pfeiffer Foundation grants totaling $3,000,000 to help meet the crucial national need for first quality medical teaching. Other institutions benefiting are Harvard Medical School, the Menninger Foundation's School of Psychiatry at Topeka, Kansas, and the University of Pennsylvania Medical School.

The grants constitute the largest allocation of its capital funds ever made by the Pfeiffer Foundation. The gift to Stanford marks the first time the Foundation has made such a large grant to higher education on the West Coast.

The new chair will honor the late Emma Louise Pfeiffer Merner, the sister of Gustavus A. Pfeiffer, industrialist and philanthropist of Iowa and New York. In 1942 Mr. Pfeiffer and his wife established the foundation, with the announced purpose of benefiting mankind through support of the medical and pharmaceutical sciences.

"The Pfeiffer Foundation grants are a magnificent contribution to the whole human family," commented Stanford President Wallace Sterling. "Research and teaching have become inseparable and vital functions of medical schools. The emphasis put upon the teaching function by this forward-looking philanthropic group at a time when health research funds are relatively abundant is of essential value to all higher education."

Dean Robert H. Alway of the School of Medicine commented, "This significant gift clearly recognizes the basic importance of assuring support for men as well as projects."

Dean Alway said that the Emma Pfeiffer Merner Professor of the Medical Sciences will be a teacher whose work is at the frontier of medical knowledge and understanding in the basic medical sciences.

(more)

The grants grew out of a two-year study into the most effective role the small foundation can play in this era of massive spending by the government for medical research. The Pfeiffer Foundation study disclosed little support of medical teaching, particularly at top levels where research grants supply only a very small percentage of salaries.

A Foundation spokesman said the Pfeiffer directors hope their grants "will stimulate other medical foundations to similar action and result in a multiplication of adequately endowed teaching chairs in the American medical colleges."

The Foundation cited a survey of 87 medical schools, showing a total of more than 800 budgeted teaching posts which cannot be filled, to illustrate "how desperately medical teaching needs to be bolstered."

The physicians of tomorrow will not have the guidance of great teachers they need if interesting and remunerative fields continue to draw these men away from teaching, it was pointed out.

Emma Louise Pfeiffer was born in Cedar Falls, Iowa, April 26, 1860, and lived there for 63 years. After the death of her husband, David C. Merner, a pharmacist, to whom she was married in 1882, she moved to California in 1923 to be with her family in Palo Alto.

The Merner and Pfeiffer families have had Stanford connections extending over three generations. Mrs. Merner is described by those who knew her intimately as a gracious and lovable woman of strong influence in a family with a long matriarchal and philanthropic tradition.

The Emma Pfeiffer Merner Professorship is the eighth of 15 new chairs to be endowed in Stanford's current PACE Program--a $100 million Plan of Action for a Challenging Era. The gift will bring to the University for its general use an additional $166,666 in matching funds from the Ford Foundation. During the PACE campaign, the Ford Foundation is providing one dollar for each three received from other private sources.

END ADVANCE FOR RELEASE SATURDAY, SEPTEMBER 14, 1963.

SPECIALIST IN HEARING DEFECTS TO JOIN STANFORD FACULTY

One of the country's leading specialists in hearing and hearing defects, Dr. Earl D. Schubert, will join the faculty of Stanford University School of Medicine next July.

He will direct a new postdoctoral training program in audiology which will be established by the Division of Speech Pathology and Audiology next summer. He will have the rank of professor.

Only a few such programs exist in the United States. It is being supported with a $37,545 grant from the National Institute of Neurological Diseases and Blindness. The grant will be used to pay for salaries, postdoctoral fellowships and research.

Dr. Schubert has a wide knowledge of all aspects of audiology. He is particularly interested in psychoacoustics (why we hear sounds the way we do) and the neurology and physiology of hearing. Although Dr. Schubert has extensive clinical experience, his main interest is research and he has published many articles in professional journals.

Since 1960 Dr. Schubert has been professor of audiology at Indiana University. From 1955 to 1960 he was professor of audiology and associate in medicine at Western Reserve University and coordinator of research at the Cleveland Hearing and Speech Center.

Dr. Schubert came to Stanford in the summer of 1962 as a visiting professor of speech pathology and audiology. He has also taught at the State University of Iowa and the University of Michigan.

Dr. Schubert received his B.S. from Manchester College in 1938 and his M.S. and Ph.D. from the State University of Iowa in 1942 and 1948 respectively.

STANFORD TEAM CONDUCTS UNIQUE ALASKAN HEART CLINIC

Evelyn is a small four-year-old Eskimo girl. Until recently she was so fragile and delicate she did not have the energy to play with her friends.

That is now changed. Last summer an Alaskan service doctor saw her in her native village of Kotzebue far above the Arctic Circle and decided she had a heart defect.

Within the month she was seen by a four-member team of specialists from the Stanford University School of Medicine -- not in Palo Alto but in Alaska where the specialists conduct a unique heart clinic for a few days each year.

Members of the team are Dr. Herbert L. Abrams, professor of radiology and director of the division of diagnostic radiology; Dr. Frank Gerbode, clinical professor of surgery; Dr. Herbert Hultgren, associate professor of medicine and director of the division of cardiology; and Dr. Saul J. Robinson, clinical associate professor of pediatrics.

Although Alaska is the largest state in the Union, it is the smallest when it comes to population and cannot support medical specialists in every field. As a result there is no place where the exact condition of certain types of heart patients (such as Evelyn) can be determined. These include many different kinds of congenital and acquired cardiac disease.

- more -

Each year physicians in Alaska come across over 100 such cases. Rather than refer each patient to physicians in other states, which would be prohibitively expensive and unnecessary in some cases, Dr. Gerbode decided to bring the doctors to the patients. Six years ago the first cardiac team flew from the Bay Area to Anchorage and initiated this unusual screening program.

The clinics are sponsored by the Alaska Heart Association and the state's Public Health Department. This year the team examined 170 patients in a four-day period. The cardiac screening group decides (1) if a patient has heart disease; (2) if he does, what type; (3) if the patient has to go to a medical center for further diagnostic tests or surgery; and (4) if the patient can be treated in Alaska. In Evelyn's case, the doctors felt she needed complete corrective surgery. This was later performed and she will now lead a normal life.

In addition to the service it renders patients, the group acts in a teaching capacity. Local and army doctors spend as much time as they can at the clinical sessions for the learning experience. Each day one of the visiting specialists gives a scientific paper on the latest advances in the treatment of heart conditions.

The team usually conducts the clinic in Anchorage, although it has also been held in Fairbanks and Sitka. This year the four Stanford physicians were made honorary members of the Anchorage Medical Society in recognition of their services.

FOR RELEASE FRIDAY, OCTOBER 25, 1963

Stanford University Friday dedicated its new Frederick W. Dohrmann, Jr., Memorial classrooms and amphitheaters in the School of Medicine and announced in conjunction a major gift of $250,000 which paid for the rooms.

The gift from Mr. and Mrs. John C. Cosgrove of Los Angeles was made as a memorial to Mrs. Cosgrove's father, Frederick W. Dohrmann, Jr., of San Francisco. It covers the cost of five classrooms and two amphitheaters in the medical school building, ranging in seating capacity from 42 to 150. The amphitheaters are considered to be among the most advanced in the country for their acoustics and seating arrangement.

In announcing the gift, Stanford President Wallace Sterling said:

"The gift from the Cosgrove family honors the memory of a distinguished business man and public-spirited citizen. It is a boon to the Stanford School of Medicine and those who learn and teach there. It is a gratifying manifestation of the encouraging support Stanford receives from the Los Angeles area."

The recent contribution to the University is in addition to an earlier gift of $75,000 made jointly by the Cosgroves and Marsh and McLennan-Cosgrove and Company to endow the John C. and Emilie D. Cosgrove Fellowship Fund. The fund supports fellowships in the Graduate School of Business.

- more -

Cosgrove, a Stanford graduate in 1934, has been active among volunteer alumni groups working to increase the University's financial support. In the current Stanford PACE program -- a $100 million Plan of Action for a Challenging Era -- he has been working with the major and special gifts committees in the Los Angeles area. His wife, the former Emilie Blanca Dohrmann, was graduated at Stanford in 1933. The couple's two daughters, Carole and Julie, are also Stanford alumnae.

Frederick W. Dohrmann, Jr., for whom the new medical school facilities were named, was president of Nathan Dohrmann Company and a leader in the economic, civic and educational life of San Francisco. He was a long-time member of the San Francisco Board of Education and served as its president. He was also a founder and president of the pioneer mercantile firm of Parmelee-Dohrmann Company in Los Angeles and San Diego. He had been educated at St. Ignatius in San Francisco and the University of Berlin. He died in 1936.

NOTE TO EDITORS: For release at 9 a.m. Monday, Oct. 28, 1963. Release time is set to follow presentation of a paper by Dr. Lower at the annual Clinical Congress of the American College of Surgeons in San Francisco. Dr. Lower will attend a news conference in the Hunt Room of the Hotel Fairmont at 3:15 p.m. Sunday, Oct. 27, and will be available for questions at that time.

HEART VALVES SUCCESSFULLY TRANSPLANTED IN ANIMALS

A dog lived at Stanford Medical Center for two years with an essential heart valve that had been transplanted from another animal, two Stanford University School of Medicine surgeons said today.

The successful case, as well as other studies, indicates that living valves may prove much more durable than artificial ones made of synthetic materials, according to Dr. Richard Lower and Dr. Norman Shumway.

The surgeons said that transplants may prove particularly useful in helping patients with mitral or aortic valve disease, frequent complications of rheumatic fever. The dog experiments were all grafts replacing the mitral valve, which is located between the upper and lower chambers of the left side of the heart.

Dr. Lower added that the currently used artificial valves have drawbacks which living grafts may overcome. Patients with artificial valves tend to develop blood clots, there is difficulty getting a perfect connection between living and nonliving material, and the valve material tends to wear out with the constant motion of the heart.

- more -

A report of the Stanford research was made in San Francisco at the Clinical Congress of the American College of Surgeons. Dr. Lower is an instructor in surgery, Dr. Shumway an associate professor.

Sixteen dogs lived more than one month after receiving transplanted valves. Microscopic examination of the valves taken on autopsy showed that the transplants apparently act like corneal grafts for the eye.

The foreign tissue is rejected very slowly. The foreign cells are gradually replaced by cells from the recipient, and the tissue continues to live.

Most bodily tissue is rejected when grafted to another individual, dying within a few days or weeks. There are only a few exceptions, such as the cornea, bone and blood vessels.

Mitral and aortic valve replacements are particularly important because the disease can be so bad that only a substitute will work. In some cases of mitral disease, the hardened flaps may be cut open, but if the condition recurs little can be done without replacing the valve.

Without some sort of relief, patients are weak, short of breath, and often must stay in bed.

The aortic valve is at the opening of the last pumping chamber of the heart and leads into the major vessel carrying blood to the body.

Commenting on the research results, Dr. Lower said, "The big question in the next few years will be whether living tissue grafts will prove more successful than synthetic materials or artificial devices.

"So far, this is the only study in dogs which fairly clearly establishes that a valve from another animal can work for two years -- and possibly indefinitely. It seems very possible that transplants will succeed the synthetics if the living grafts prove durable."

Grafts of valves have been attempted in humans a few times in other countries. However, there have been no published results of successful operations, although results of some studies are not available, Dr. Lower indicated.

Sixty-five students have enrolled in the first-year class at the Stanford University School of Medicine -- nine more than were enrolled last year.

The class of 1968 is composed of 57 men and 8 women representing 17 states and the island of Tobago in the British West Indies. Only 23 of the 65 are residents of California.

The new students come from 37 colleges in 17 states and 57 already have college degrees. Seventeen of the students attended Stanford University.

Following is a list of the new students with their parents' names and home addresses:

ARIZ., PHOENIX - Thomas H. Brzozowski, Mr. and Mrs. Joseph S., 5381 W. Osborn Rd.
William M. Johnson, Mr. and Mrs. Loren E. Johnson, 726 W. Latham.
Herbert Poetzl, Mr. and Mrs. George A. Poetzl, 333 W. Hazelwood St.
Alan R. Tempkin, Mr. and Mrs. Elliot H. Tempkin, 501 West Holly.

CALIF., BELMONT - Joan Louise Voris, Dr. and Mrs. Albert T. Voris, 1703 Belburn Dr.
BERKELEY - Virginia J. Borson, Dr. and Mrs. Harry J. Borson, 244 Alvarado Rd.
Barry L. Mendelsohn, Dr. and Mrs. Matthew Mendelsohn, 39 Highgate Rd.
BEVERLY HILLS - Jeffrey S. Stevens, Mr. and Mrs. David R. Stevens, 1003 N. Rexford Rd.
HEMET - Joseph S. Wakefield, Jr., Mr. and Mrs. Joseph S. Wakefield, Sr., Rt. 3, Box 244
HILLSBOROUGH - Robert H. Friedman, Mr. and Mrs. Nathan J. Friedman, 475 Pepper Ave.
LA JOLLA - Fred H. Burbank, Mr. and Mrs. Forrest Burbank, 1365 W. Muirlands Dr.
LOS ANGELES - Kai Haber, Dr. and Mrs. Heinz Haber, 322 S. Canyon View Dr.
MOUNTAIN VIEW - William G. Hayden, wife Dolores Hayden, 2250 Latham.
OAKLAND - Maria Viola, Mr. and Mrs. Vito Viola, 12669 Skyline Blvd.
ORANGE - James A. Davis, Dr. and Mrs. Perry Davis, 12872 Woodbury Dr.
ORINDA - William R. Cline, Mr. Wilson G. Cline, 518 Miner Rd.
PALM DESERT - Dale J. Cox, Mrs. Ruthanna Cox, 45-674 Toro Peak Rd.
PALO ALTO - Ronald Levy, Mr. and Mrs. Herman H. Levy, 420 Hale St.

AREA RESIDENTS SPONSOR VISIT OF TWO PERUVIAN MEDICAL STUDENTS

Two interns from Peru's National University at Trujillo will study for three months at Stanford Medical Center, thanks to the joint efforts of local residents.

The interns, Augusto Chang and Orlando Hernandez, will spend part of their study in their chosen specialty and part in the medical school's infectious disease control program.

Chang has chosen to specialize in obstetrics and gynecology "because of the high mortality rate in mothers and newborn infants caused by the lack of obstetrical care in Peru."

Hernandez is studying to be an internist. He entered medicine "because doctors are so badly needed in Peru." He noted that Peru has only one doctor to 2400 persons compared to one to every 790 in the United States.

The idea for their visit originated with Dr. Theodore Myers of San Mateo while he was in Peru last year arranging for the hospital ship HOPE to visit Trujillo. Dr. Myers, a clinical instructor in medicine at the Stanford University School of Medicine, arranged to have Ernie Altekruse and John Cutting, two Stanford medical students, on the ship. At Dr. Myers' suggestion, the students invited the Peruvian interns to study at the Center.

Two Palo Alto physicians have invited the Peruvian students to live in their homes. They are Dr. Howard L. Jones of 372 Walsh Road, Atherton, and Dr. William Clark of 859 Northampton Drive, Palo Alto.

Plane fare for the visitors was paid by their own university. The Stanford University School of Medicine has absorbed the cost of their special training. The Palo Alto Medical Staff contributed funds to provide for incidental expenses.

STANFORD ANATOMIST NAMED TO HEAD STUDENT AFFAIRS PROGRAM

Dr. Donald Stilwell has been appointed assistant dean for student affairs at the Stanford University School of Medicine. He will also continue his duties as associate professor of anatomy at the School.

In his capacity as assistant dean, Dr. Stilwell is chairman of the committee in charge of the student advisor program, heads the 13 premedical student advisors on campus, and will handle institutional grants to students.

Since coming to Stanford in 1949 as an instructor, Dr. Stilwell has taught neuro- and gross anatomy, as well as a relatively new program in surgical anatomy conducted in cooperation with the Division of Rehabilitation Medicine and various divisions of the Department of Surgery.

Dr. Stilwell is also resident advisor at Stanford's Wilbur Hall, a freshman dormitory.

A native of Detroit, Michigan, Dr. Stilwell got his B.S. and M.D. at Wayne State University in that city in 1941 and 1944, respectively. He is the author of numerous articles in professional publications.

Dr. Stilwell replaces Dr. Seymour Kolko, who resigned in January to become director of the Belmont Hills Neuropsychiatric Center.

NOTE TO EDITORS -- For release at 3 p.m. Thursday, November 21. The release time is set to follow presentation of a paper by Dr. Wilmer at 62nd meeting of the American Anthropological Association at Sheraton Palace Hotel, San Francisco.

SAN FRANCISCO -- Neither punishment nor rehabilitation programs will be effective in reducing crime as long as society prefers to label offenders as evil and continues to punish them at all cost.

Dr. Harry A. Wilmer, clinical associate professor of psychiatry at Stanford University School of Medicine, expressed this view in a report to the 62nd meeting of the American Anthropological Association here.

Dr. Wilmer, who is also a consultant to the California Department of Corrections, cited statistics showing that over 40 per cent of the parole violators return to prison with a new criminal committment.

"Once a man enters prison it is almost a fifty-fifty chance that prison will again be his way of life," Dr. Wilmer said.

This is because prison culture hardens most criminals rather than rehabilitates them, the psychiatrist said. Society views them with terror and deprives them of jobs and their civil rights.

"Of the 5,000 men in San Quentin," he noted, "society does not judge them according to their crimes but according to their incarceration. In the prison, there are the good guys, prison officials, and the bad guys, inmates.

"The distinction is inevitable and a tense and potentially dangerous situation follows with one segment preoccupied with security measures and the other thinking of freedom and escape. The prisoners, caught in the morass of loneliness, defeat, humiliation and fear, are welded together strengthening the bad guy identifications with a driving wish for revenge."

- more -

It follows, Dr. Wilmer said, that in this state of mind, most prisoners instead of working conscientiously toward their release, adjust to the world of prison as the only existence in which they can live successfully.

Detention, however, may serve a much more important purpose, Dr. Wilmer said. It may serve the function of separating the offender from his wounding environment long enough for the psychiatrist and him to take a new view of the matter.

With this in mind, prison officials and rehabilitation experts met at Soledad State Prison in 1959, and decided to implement an extensive test of the "therapeutic community concept" in California prisons, Dr. Wilmer reported. This concept of treatment, now in use in some psychiatric hospitals, describes a technique for handling mental patients by giving them near-normal group freedom.

In May 1961, the first organized therapeutic community experiment was established by the State Department of Corrections at San Quentin prison. Its purpose was to expose a selected group of inmates to intensive social group therapy in the hope of increasing their parole success.

During the first 27 months of its operation 172 men entered the program. They were selected on the basis of a median score of the Base Expectancy Test which allows clinicians to predict whether an offender will make a favorable parole adjustment. Their average age was 30.

The men were on minimum custody and lived on the ranch just outside the walls of the main prison. They slept in dormitories, ate in a common mess hall, and worked together as they would in a normal community.

The staff in the program included two full-time prison counsellors, a full-time correctional officer, and a psychiatric consultant one full day a week. The staff was augmented by a psychiatric resident from the Stanford University School of Medicine who participated as part of his training.

Both prisoners and staff met daily after the inmates' regular work in the prison. The unit was divided into five small groups that met twice a week. It included an orientation group for newcomers, and a pre-parole group for men who were soon to be released.

In addition, there was a husband and wife group which met once a week with the staff and the psychiatrist.

"All the meetings were informal and were conducted with a minimum of staff direction. For the most part, the discussions concerned the immediate behavior problems in the community," Dr. Wilmer said. "However, crime, prison, and parole recurrently dominated the discussions. A guiding principle was to attempt to maximize participation by widening the focus of individual problems to those which all men face."

Of the 172 offenders who participated in the therapeutic community experiment, 92 were paroled, Dr. Wilmer reported. Their average stay in the program ranged from six to 18 months. Of these, only 21 offenders were parole failures over a two-year period observed.

If the percentage of parole violators continues to remain low, Dr. Wilmer added, the results will be outstanding.

An important element to the favorable outcome was the use of San Francisco's Intensive Parole agent unit as a bridge to the community. The parole officers went regularly to the prison meetings, and the prisoners were allowed to choose their parole officers if they wished.

Buoyed by this seeming progress, the State Department of Corrections has extended the therapeutic community idea to prisons throughout the state. There are more than 1,000 men and women in what is known as the Increased Correctional Effectiveness program.

- more -

Dr. Wilmer hopes that this experiment will give new insight and direction to better rehabilitation programs. "The alternative," he said, "would be merely repeating costly failures."

Considering that there are 25,000 felons in California state prisons, the prison population studied was infinitesimal. Yet, he added, the incarceration of 172 prisoners represents an expense to society of between one and two million dollars. Aside from their victims, there are their families which share in the distress, shame, and guilt.

"Rehabilitation research is no frill," he said, "but an investment society must make for its own safety."

Thanks to the crusading efforts of a Stanford Medical School physician and to the support of the state public health department, disabled persons in rural communities may shed their unhappy reputation as one of the "least cared-for groups in California."

This description comes from Dr. Daniel J. Feldman, director of Rehabilitation Medicine, who believes that a man torn from his life's work by a disease or a crippling accident deserves at least a chance and that disability need not be the end -- but a challenge for a new beginning.

Each year approximately 400,000 Californians suffer disabilities which cut them off from normal activity. The disabled are those who suffer from arthritis, congenital defects, injuries from accidents or strokes, mental illness, heart disease, polio, multiple sclerosis or other such incapacitating conditions.

Those who are lucky enough to live near a medical center, with active rehabilitation programs, may benefit from the latest techniques and return to society totally or partially restored.

But most of the disabled who live in California's rural communities are penalized because rehabilitation specialists are scarce.

When Dr. Feldman surveyed their status a year ago, he found conditions grim. They still are mostly unchanged today, but in such selected counties as Colusa, Shasta, Modoc, and Monterey, pilot physical rehabilitation clinics, set up by Dr. Feldman at the request of local physicians, have begun to alleviate many of the worst problems.

- more -

For example, a 21-year-old patient from Alturas, thought to be severely disabled by multiple sclerosis, was found lying in a county hospital. He was brought to the Stanford Medical Center for tests which revealed that he suffered from a brain tumor. An operation was performed and the tumor was removed. The patient partially regained his speech and hearing. After a few months of rehabilitation treatment at the Center, he returned home and was able to live with his family under minimum care.

Since the clinics began more than 30 patients have turned up who were able to benefit from Stanford's rehabilitation services. This fact also brought outright support from the physicians in rural communities, who have welcomed these clinics.

Before each clinic, physicians in the county prepare a list of rehabilitation patients to be seen by the Stanford team. The team consists of a physiatrist (a specialist in rehabilitation medicine), occupational therapist, physical therapist, social worker, and a rehabilitation nurse.

The Stanford physiatrist and the local doctors examine each patient and make a joint diagnosis; then they decide on a course of treatment.

Dr. Feldman said that it is not feasible for many rural counties to reproduce the kind of rehabilitation center that exists at Stanford. But it is quite feasible to carry out much of the necessary rehabilitation locally with the help of the specialists from the medical center.

The pilot clinics, he noted, have aided local physicians in bearing the responsibility of rehabilitation. Experience gained from these clinics will guide the Stanford School of Medicine in the development of training programs for rehabilitation personnel.

The clinics also will allow the Stanford team to study the rehabilitation needs of a representative number of rural communities, and to observe patients in their own surroundings.

"Many disabled persons," Dr. Feldman said, "would respond more rapidly to treatment in their own surroundings rather than in the impersonal atmosphere of a large hospital."

The clinics may serve a preventive function, too. Successful amputation of a leg, for example, does not end with the healing of the stump. The amputee needs an artificial limb, training in its use, social services designed to reassure him about his family's welfare, vocational counseling, and psychiatric help in accepting himself as a disabled person.

"We want to find out what we can do to prevent other problems from piling on the already disabling features of the disease," Dr. Feldman said.

If the rural rehabilitation clinics prove successful, Dr. Feldman foresees a wider use of them in the future. "It is a pattern of medical care that will be most practical for California and maybe other places," he said.

In addition to Dr. Feldman, staff members from the Stanford Medical Center who have taken part in the clinics are Dr. Jose Montero, assistant professor of rehabilitation medicine; Mrs. Helen Schwedenberg, occupational therapist and program coordinator; Miss Helen Blood, instructor in physical therapy; Gerald St. Denis, assistant professor of clinical social work, Miss Mary Alderson, rehabilitation nurse; and a number of residents in rehabilitation medicine who act as research assistants.

COMPUTER IS USED TO DIAGNOSE SKIN DISEASES

CHICAGO--Can a computer aid a doctor in diagnosing disease?

The answer is yes, according to Dr. Arthur L. Norins, assistant professor of dermatology at Stanford University School of Medicine.

Dr. Norins based his answer on preliminary studies with a computer system designed to diagnose skin diseases. The system was exhibited this week at the annual meeting of the American Academy of Dermatology in Chicago.

At this stage of development, Dr. Norins admits, he would prefer to let a medical student evaluate a patient's condition. Nevertheless, trial runs with the new system were successful.

He predicts that within ten years physicians will be depending quite heavily on computers for pinpointing patients' problems.

The Stanford system is designed to discriminate among several hundred skin diseases. For each ailment, there are 200 "attributes" stored in the computer's memory unit.

The attributes include 100 items of information about typical symptoms, physicians' observations and patients' histories. There are also 100 items about microscopic observations of tissue samples from patients with the disease.

- more -

To make a diagnosis with the computer, a physician lists the symptoms, observations, and history of the patient involved. He also lists the results of the microscopic examination. The computer compares the specific case with its "experience" and chooses the most likely disease description.

Dr. Norins admits that he is in a fortunate position as a dermatologist. Samples of diseased tissue can be obtained from the skin by a simple biopsy, and the skin can easily be examined by the physician.

Several other groups in the United States are using computers for diagnosis. This system is the first for skin ailments. It is also the first to incorporate data from microscopic examinations.

In addition to its application in diagnosis, it is being used to accumulate statistical information on dermatologic problems and in teaching students.

The computer used in the system and in the Chicago exhibit is a Control Data Corporation Model 160A. Studies so far have utilized a 160A located at the firm's branch in Palo Alto.

Eventually, Dr. Norins said, it will be possible to have teletype links between a computer center and physicians' offices to make the system easily accessible to practitioners.

Construction will start this week on a $6,150,000 clinical sciences research building for the Stanford University School of Medicine, Stanford officials disclosed today.

It will be the first major addition to the Stanford Medical Center since it was constructed five years ago. It is financed in part by Stanford University's PACE Program (Plan of Action for a Challenging Era) which recently passed its announced $100 million goal.

The new structure, which will be located between the Stanford hospital pavilion and Medical School Building, will contain facilities for investigation in medicine, surgery, radiology, pediatrics, genetics, obstetrics, and psychiatry.

It will also include the Lt. Joseph P. Kennedy, Jr., Laboratories for Molecular Medicine where basic research will be undertaken related to causes of mental retardation.

Part of the new building will house facilities, supported by the National Aeronautics and Space Administration, for research in the fields of space biology and biomedical instrumentation.

The building will consist of four stories -- a basement and three floors -- covering 152,000 gross square feet, about twice the size of existing hospital pavilions.

Funds for construction of the research facility have come from PACE program gifts and government grants for research facilities.

The largest PACE gifts were two of $1 million each from the Rockefeller and Joseph P. Kennedy, Jr., Foundations. Government grants include $2,033,918 from the National Institutes of Health, and $535,000 from the National Aeronautics and Space Administration.

The building was originally to have been built as part of the Medical Center, but when construction began in 1957 there was not enough money available.

Contractors for the building are Leon M. Wheatley, Inc., and Jacobsen Bros. Construction Company of Palo Alto, bidding as a joint venture. Edward Durell Stone of New York, is architect, with Milton D. Pflueger of San Francisco, as associate architect. The building will be ready for occupancy in the fall of 1965.

STANFORD PHYSICIAN DEVELOPS NEW ISOLATION UNIT

A new way to protect hospital patients who are highly susceptible to germs has been developed by a physician at the Palo Alto-Stanford Hospital.

Starting soon such patients will be placed in "plastic rooms," allowing doctors and nurses to care for them without coming into direct physical contact.

Present methods of protecting such a patient -- a process called "reverse isolation" (placing a patient in quarantine for his own self-protection) -- are complicated and costly. The room he occupies has to be sterilized, persons entering the room have to put on sterilized clothes, and all objects taken into the room have to be made as sterile as possible. Even then the patient may pick up a germ from a person who is not sick but a carrier.

The new plastic rooms, developed by Dr. Charles Beal, assistant professor of preventive medicine at the Stanford University School of Medicine, are throwaways. Everything, except the mattress, is outside the room. Shots can be given and blood drawn by inserting a needle through the plastic. Arm vents with rubber gloves are attached at intervals to the tent to allow for patient care.

The unit has a self-contained air supply. Air pressure on the inside is slightly higher than on the outside so that no bacteria can enter the tent. The patient receives his meals and other items through lock equipment much like that used in submarines.

Dr. Beal has also developed a reverse isolation "transportation bag." The bag, which is placed on a guerney, is attached to the plastic tent by a zipper and the patient is slipped into it much like he would be slipped into a sleeping bag. The transportation unit has its own air supply and permits the patient to be taken anyplace in the hospital in isolation.

Recently Dr. Beal received an $11,000 grant from the Northrop Aviation Company in Los Angeles for further experimental use on the isolator. He now hopes to modify it so that it can be used for both reverse and regular isolation.

New executive head of the Division of Neurosurgery at the Stanford University School of Medicine is Dr. John Hanbery. His appointment became effective January 1. Dr. Hanbery has been acting head since 1960, in addition to carrying on his own private practice.

Dr. Hanbery has many Stanford ties. He received his A.B. and M.D. at the University in 1942 and 1945, respectively. He interned and did much of his residency in surgery at the Medical School in San Francisco and from 1954 to 1959 was an assistant professor there. When the School moved to Palo Alto he was appointed clinical assistant professor. In 1961 he was promoted to clinical professor.

Dr. Hanbery has spent many years in Canada, first doing research, teaching, and neurosurgical and neurological residency work at the Montreal Neurological Institute and then as a staff member both at the Institute and Royal Victoria Hospital.

A native of Enid, Oklahoma, Dr. Hanbery now resides at 70 Mercedes Lane, Atherton. He is married and has four children.

RESPIRATORY COMPLICATIONS STUDIED UNDER $320,000 HARTFORD FOUNDATION GRANT

A research program aimed at improving the care of some of the sickest patients in any general hospital is now under way at Stanford Medical Center.

The patients are those who have severe difficulty breathing, a frequent and often fatal complication of many operations and illnesses.

The patients are being studied in a respiratory unit financed by a three-year, $320,000 grant to the Stanford University School of Medicine from the John A. Hartford Foundation of New York City. It is the first such facility to be established in northern California.

"These patients require the most meticulous hour-to-hour care of any I know, and they need it for days on end," according to Dr. John P. Bunker, director of the program. Dr. Bunker is professor of anesthesia and executive head of the Department of Anesthesia at Stanford.

Assistant Professor Grant Fletcher is in charge of the unit where the studies are being carried out. It is part of the intensive care unit in the Palo Alto-Stanford Hospital.

The third member of the research team is Associate Professor J. Weldon Bellville, who will direct investigation of the role of drugs and disease in altering the nervous system's control of breathing.

New methods of treatment will be evaluated in the study. At the same time physicians will try to gain better understanding of the course the complications may take.

- more -

Three general areas are being covered in the program:

1. Respiratory problems resulting from mechanical limitations on breathing. These may be caused by surgery of the upper abdomen, chest injuries, and diseases such as tetanus and myasthenia gravis.

Initially, postoperative patients are receiving special attention because they are particularly prone to such complications and may be studied from the time difficulties begin. According to one study, 43 per cent of surgical patients given no preventive treatment for pulmonary complications will develop some degree of lung collapse.

2. The effect of drugs and certain diseases on the "respiratory center," that part of the nervous system which controls respiration. Certain forms of epilepsy, polio, thyroid disease and liver disease affect the respiratory center. So does barbituate poisoning, which is simply an overdose of an anesthetic.

Dr. Bunker predicts that with understanding of what happens to the nervous system under such circumstances, it should be possible to prevent or lessen the likelihood of lung collapse and the pneumonia which often follows.

3. An analysis of the course of infection in patients with depressed respiration. Pneumonia is a frequent complication after lung ventilation reaches a low level. It is not known, however, whether such infections are usually caused by the patient's own germs or come from other sources.

Whether a patient falls in category 1 or 2, he will usually recover if physicians are able to keep him breathing. But this requires an estimated eight times as much individual care, from physicians and nurses, as given on a general care ward.

Anesthetists are particularly suited for such a project, Dr. Bunker said, because of their wide experience dealing with breathing difficulties in the operating room. In assisting their patients they have had to develop new methods of management which are applicable to disturbances of respiration in nonsurgical patients.

The grant brings to $1,500,000 the amount awarded by the John A. Hartford Foundation, Inc., to the medical school for support of research and clinical programs.

The Hartford Foundation was established by John A. Hartford, former president of the Great Atlantic and Pacific Tea Company, who left it the bulk of his estate. His brother, George L. Hartford, former chairman of the board, left his entire estate to the Foundation.

The California Elks have granted $25,000 to the Stanford Medical Center for the care of needy handicapped children.

The gift would pay for the care of 50 children in the Palo Alto-Stanford Hospital, Stanford Clinics, and the Stanford Convalescent Home in 1964. It would also cover expenses for drugs, laboratory tests and, in some cases, transportation and housing expenses for the parents if they must remain in the area while their child is being treated.

In announcing the gift, Walter J. Schween, Jr., of Salinas, a trustee of the California Elks Major Project, Inc., said: "We are very happy to bring this service to needy handicapped children and hope that it will be of lasting benefit to them."

The gift would cover children suffering from conditions affecting their normal growth, chronic kidney disease, blood disorders, respiratory disease, emotional problems associated with handicaps, birth defects, orthopedic problems, and diseases of the eye.

Patients accepted in the program will be recommended by referring physicians and screened by social workers at the Medical Center.

The program will be under the direction of Dr. Norman Kretchmer, head of the Department of Pediatrics of the Stanford University School of Medicine.

This is the first major charitable venture by the California Elks in the field of inpatient care, Schween said. For the past 13 years the California Elks Major Project, a nonprofit corporation for aiding physically handicapped children, has been instrumental in providing physical therapists for the handicapped in rural areas.

Laboratories for investigating new techniques for surgery of the nerves and brain will be built at Stanford Medical Center with a gift from the Euphrat family of San Francisco and the Peninsula, Dean Robert H. Alway of Stanford University School of Medicine announced today.

One of the aims of the researchers working in the laboratories will be to develop new techniques of operating on tumors of the brain. Methods to be tried will include freezing and use of electronic beams or electrical probes which will destroy tissue.

E.F. Euphrat, San Francisco business and financial leader, and his sons, Jack S. and Edward F. Euphrat, joined in memorial gifts and pledges for the facilities in the new Clinical Sciences Research Building now under construction. There will be laboratory and office space for seven faculty members and postdoctoral fellows.

The Euphrat laboratories are being donated in memory of Helen E. Euphrat, and--at the request of her two sons--it will also honor her husband and their father, E.F. Euphrat. Mrs. Euphrat died Dec. 13, 1963.

E.F. Euphrat, who now heads his own securities firm in San Francisco, was founder and for many years president of Pacific Can Co. His sons are graduates of Stanford University and have been active in community and civic affairs.

NOTE TO EDITORS: Two sample photos from the display are available from the News Bureau. Prints of the other photographs to be shown may be obtained from Stifler.

"FACE OF POVERTY" PHOTO STUDY TO GO ON DISPLAY AT STANFORD

Richard Stifler, a third-year Stanford medical school student who went to El Salvador last year as a member of a project studying hospital infection, spent as much or more time on another project only indirectly related to medicine.

One of the results of this second project -- a photographic study called "The Face of Poverty" -- will go on display Sunday (FEB. 23) in the Main Library at Stanford University. The show will continue through March 7.

After previewing the pictures, Daniel M. Mendelowitz, professor of art and education at Stanford, commented that "Mr. Stifler's deepest concern was with the people who were the subjects of these eloquent documentary photographs. The results are deeply moving, with the strength of unselfconscious force and honesty."

Stifler will also give a talk about his experiences in Central America. Sponsored by the Department of Medicine, it will be held in room 282 of Tresidder Union at 4:15 p.m. March 2. The talk is open to the public.

The display represents only one aspect of the photographs taken by Stifler last summer and during a subsequent trip to the Latin American republic in December.

He plans one more trip in July, at which time the pictures will be compiled into a book to be co-authored with Dr. David Burleson, a visiting professor of anthropology at the University of El Salvador.

The purpose of the book and the show is to educate Americans and others about the living conditions in an "underdeveloped" nation.

- more -

"It is only incidental that these pictures were taken in El Salvador," Stifler said. "The conditions they portray are typical of two-thirds of the world's population."

Stifler, 24, is the son of Mr. and Mrs. Robert Stifler of Phoenix, Arizona. He received a B.S. in biology at M.I.T. before coming to Stanford.

He admits he is drawn strongly toward Central and South America. "I love the area; it's hard to put into words just why. I like the dignity of the people. It shows in my pictures, even though the people are so poor. And there is great beauty in their country and their language."

He also feels that it is possible to make a real contribution in Latin America. "There is a shortage of educated people. If you are interested, you can play an important part in the development of a country such as El Salvador."

Stifler originally went to El Salvador to help study a method of controlling hospital "staph" infections in newborn babies. The project was under the direction of Dr. Harold Simon, assistant professor of medicine at Stanford University School of Medicine.

One part of the research involved taking bacterial cultures from mothers and children after they had returned home. It was during visits to many parts of San Salvador, the country's capital, that Stifler developed the interest which led to the photographic study.

Localized cancers can now be treated with intensive doses of drugs concurrently with intensive radiation therapy, according to Dr. Malcolm Bagshaw, associate professor of radiology at the Stanford University School of Medicine.

For the past two years he and two of his associates, Dr. Thomas Nelsen, assistant professor of surgery, and Dr. Saul Rosenberg, assistant professor of radiology, have been investigating the feasibility of using this type of combined therapy on patients with cancer so advanced that it can neither be operated on nor treated with radiotherapy.

Their findings were reported to the 1964 Science Writers Seminar of the American Cancer Society today (March 24) by Dr. Bagshaw and Dr. Henry Kaplan, head of the Stanford medical school's Department of Radiology.

Certain drugs such as purine and pyrimidine analogues may render cells more sensitive to X-ray therapy. The investigations carried on by Dr. Bagshaw and his associates have been designed to find out if the human body will tolerate a combination of drugs and X-ray treatments for long periods of time. Treatment of 30 patients with neck cancers and 10 with pelvic cancers, the areas best suited to this approach, indicate it can, Dr. Bagshaw reported.

Dr. Nelsen inserts catheters into the artery supplying blood to the tumor area, insuring a high concentration of the drug where it is needed and minimizing its general circulation. Because the pressure of the arteries is so great, he had to devise an electrical pump system with its own power supply which would slowly force the drug into the artery. The power supply is portable and enables the patient to be completely mobile.

- more -

The researchers have found that patients are able to tolerate catheters in their arteries for as long as eight weeks with little discomfort.

They usually receive the drug eight hours a day and a heparin solution the rest of the day. The latter is given to keep arteries open. Dr. Bagshaw says patients can safely be given the drug concurrently with X-ray therapy for as long as six weeks.

Although the study is designed to find out if this method of treatment is feasible and not as a statistical study of treatment drugs, Dr. Bagshaw notes that in 18 of the first 22 patients receiving this type of combined treatment the cancerous tumor started regressing.

One of the first patients to receive this type of treatment, a 42-year-old housewife, was thought to have an incurable cancer of the throat which had already spread to her neck glands. Since being treated, her tumor has disappeared with no signs of returning. However, Dr. Bagshaw stresses the fact that it is still too soon to judge the effectiveness of the combined therapy. Most of the patients have been under treatment for a relatively short period.

Combining drugs with X-ray therapy is just one type of experiment being conducted in the 15-bed cancer research unit at the Center. The unit, completely supported by a grant from the National Institutes of Health, has been set up to study various new methods of carrying on X-ray therapy of cancer patients.

By simply using a thread, physicians can measure their patients for lack of stomach acidity, according to Dr. Charles Beal, assistant professor of preventive medicine at the Stanford University School of Medicine.

He has developed a simple device which consists of cotton thread impregnated with Congo red dye coiled in a gelatin pharmaceutical capsule. One end of the thread protrudes through a hole in the capsule. The physician holds the thread as the patient swallows the capsule which carries the thread to the stomach.

Within one minute the capsule dissolves and the thread is quickly withdrawn. If the Congo dye remains red, it indicates the person who swallowed the thread has very low stomach acidity. If the color changes to purple or black, the person has a normal or above normal amount of acid.

Low acidity in a person's stomach is sometimes associated with pernicious anemia or stomach cancer, Dr. Beal pointed out. The new capsule does not give an exact measurement of stomach acidity, i.e., it does not indicate excess acidity, a frequent accompaniment of peptic ulcers. However, it can help a physician decide if further tests are indicated.

So far, 500 tests using the gelatin capsule have been given successfully to medical students, patients and employees at the Center.

With this device, measuring a person for lack of acidity will be as simple as taking a blood pressure reading and can become a routine part of physical examinations, Dr. Beal said.

91-YEAR-OLD PHYSICIAN VOLUNTEERS FOR AGING-FITNESS STUDY

A 91-year-old physician-physiologist whose physical fitness has astonished doctors at Stanford Medical Center is currently "playing guinea pig" in a study that may produce an unmatched record of his aging process.

The man is Dr. Percy Millard Dawson, the oldest elected member of the American Physiological Society still living, and long familiar here for his weekly hikes on the foothills back of the Stanford campus.

Dr. Dawson is unusual in two other respects. He is the best possible example of his life-long preaching and practice, that regular exercise and hygienic habits make for a healthy, lengthy life. Just 50 years ago he first tested his exercise capacity and other physiological functions on a bicycle ergometer; he has checked himself at intervals since, producing an extraordinary record of the effects of aging on his work ability.

Fortunately last year Dr. Dawson and his history came to the attention of two researchers. The two are Dr. Karlman Wasserman, assistant professor of medicine and director of the Pulmonary Function Laboratory of the Stanford University School of Medicine, and Dr. D. B. Dill, long with the Harvard Fatigue Laboratory and now -- at 73 -- a National Research Foundation research scholar in physiology at Indiana University.

Mounting Dr. Dawson once more on the saddle of a bicycle ergometer, they have repeated the tests he started 50 years ago. Among other things they measured his oxygen consumption, heart rate, blood pressure, ventilation, and mechanical efficiency, thus bridging the years with the most complete longitudinal record of one man. Their conclusions in part:

"While there is a decrease of his working capacity during these 50 years, Dr. Dawson's exercise ability at age 91 is comparable to healthy men of 60.

"So far as we know the record of Dr. Dawson is a unique achievement for his age. It is noteworthy that since college days his body weight has been constant, that he has exercised strenuously and that he has never used tobacco."

The investigators further acknowledge that "according to actuarial tables of 1,000 men who were 20 years old in 1893, only 20 are alive today. No one knows how many of these survivors would venture a 30-minute ride on a bicycle."

- more -

Dr. Dawson was born in Montreal in 1873, when Ulysses S. Grant was President of the United States; when Queen Victoria was only halfway through her reign, and when Alexander II ruled Russia.

He played lacrosse and cricket as a youth and was an avid hiker in his search of insects and fossils. He enrolled at McGill University in 1889, but was driven south by recurring winter bouts of bronchitis. He ended at the Johns Hopkins University, where he earned his A.B. and M.D. degrees. For four years he played varsity lacrosse.

"I made training for this an all year process," he recalls now. "I continued such year-round training with more or less strictness all the rest of my life. The result was that, for a person with a sedentary occupation, I could do remarkable feats of endurance -- nothing Olympic, but things out of the ordinary in hiking over the mountains and plains."

After obtaining his M.D. Dawson remained at Hopkins from 1898 to 1909, rising to associate professor. In the latter year settlement work in the slums of Baltimore led him to the conclusion that "while Science is so splendid, Society is so awful; it has to be straightened out or we shall all be lost."

To help, he enrolled at Harvard Divinity School in 1910, and emerged two years later as a Unitarian minister. But the call of physiology was too strong; after a year as a pastor to a church at Ann Arbor, Mich., he joined the faculty of the University of Wisconsin.

There he shifted his interest from physiological research to the physiological aspects of physical education and wrote a book which was once widely used as a college text. It was called The Physiology of Physical Education for Physical Educators and Their Pupils. A chatty sort of book, it was written in simplified spelling, one of Dr. Dawson's long-time enthusiasms.

Later Dr. Dawson taught for a time at Duke and -- as late as 1951, when he was 78 -- at Stanford. He still works a hard lively day at his home in Los Altos (where he lives with his second wife) writing his autobiography, and caring for his garden.

Although 15 years ago he "had found hiking inconvenient and given it up," he resumed it in 1952 when, at a Harvard alumni dinner in Palo Alto, he met Augustus Locke, now 81, a noted geologist.

"In spite of his advantage in age and strength," says Dr. Dawson, "he was willing to humble himself to my speed in hiking, and so we became an inseparable pair. We walk all year once a week on the mountain roads. At first it was eight miles, later only six . . . . The bicycle ride at Stanford was a magnification of these walks."

# # #

NOTE: Dr. Dawson's address is 107 E. Portola Ave., Los Altos
Dr. Locke lives at 1275 San Mateo Dr., Menlo Park

NOTE TO CITY EDITORS

On Thursday, March 12 Stanford University's School of Law and the Department of Psychiatry of the School of Medicine will present a lecture by the Honorable David L. Bazelon, chief judge of the United States Court of Appeals for the District of Columbia.

He will speak on "The Interface of Law and the Behavioral Sciences" at 8:30 p.m. in Room M106 at Stanford Medical Center. The meeting will be open to faculty and students. Members of the press are also invited.

Judge Bazelon is the author of the opinion of the United States Court of Appeals in Durham v. United States in 1954. In this case he formulated the rule that "an accused is not criminally responsible if his unlawful act was the product of a mental disease or mental defect."

He received the Isaac Ray Award for 1960-61, given annually by the American Psychiatric Association for contributions to the improvement of relations between law and psychiatry.

In 1957 Judge Bazelon received a certificate of commendation from the A.P.A. for bringing to American jurisprudence through his opinions "the concept that when criminal acts are perpetrated as a result of mental illness, the courts will consider the nature of the illness of the accused."

Judge Bazelon is also a lecturer on psychiatry and law at the University of Pennsylvania and a member of the United States Judicial Conference Committee on the Administration of Criminal Law.

If your reporter will come to the information desk in the main lobby of the Stanford Medical Center, 300 Pasteur Drive, Palo Alto, the information clerk will direct him to the lecture room.

NOTE TO EDITORS: This release is about the Stanford Medical Center's Institute for Childhood Aphasia which is supported by a continuing grant from the California Scottish Rite Foundation. The Foundation is holding a state-wide workshop to be followed immediately by its annual meeting Saturday, March 7, at the Sutter Club in Sacramento.

Four-year-old Johnny could neither speak nor understand words when he came to the Stanford Medical Center's Institute for Childhood Aphasia. Seemingly, his only interest in life was sitting in a rocking chair and humming to himself. He had all the symptoms of a mentally retarded child.

Now, only six months later, Johnny is an alert youngster able to associate words with pictures. There is a good chance that by the time he is six he will be able to enter the first grade and compete with other children his age.

Johnny is one of thousands of children in the U.S. with aphasic language disorders. Aphasia is caused by brain damage which impairs a child's ability to speak and, in some cases, to comprehend written and spoken language. Unlike some forms of brain damage, it does not often impair a child's intellectual potential.

The causes of childhood aphasia usually occur prenatally. In many instances, however, aphasia may occur in children under two years of age -- before they have had a chance to establish normal language patterns. Often aphasia is complicated by emotional and social problems. It is therefore frequently necessary to distinguish between aphasic and emotional disturbance.

For these reasons Johnny's case was unusually difficult to identify and evaluate. Johnny's father does a considerable amount of traveling and his mother seems to be unable to deal with "normal" children, much less one with Johnny's problems. In this case the mother has to be counseled while Johnny receives treatment.

The Institute for Childhood Aphasia, a unit of the Division of Speech Pathology and Audiology at Stanford University School of Medicine, was established in September 1962 with a continuing grant from the California Scottish Rite Foundation to investigate such problems. The Institute is headed by Dr. Jon Eisenson.

Objectives of the Institute are to treat severe cases of aphasia, develop special training techniques, train personnel to understand and work with the many manisfestations and problems presented by aphasic children, and counsel parents of such children.

- more -

One of its most important functions is in diagnosis and suggested treatment for children who will not continue in the Institute for training. Children in this category have been referred from the western part of the U.S., Alaska, Canada, and several foreign countries.

The Institute cooperates closely with the Stanford medical school faculty. Each child who comes to the Institute as a patient, or for evaluation, routinely receives a pediatric and a neurological examination, including an EEG, and an audiological examination. He is referred to other departments when necessary (frequently a psychiatric evaluation is indicated).

Staff members at the Institute give each child a battery of diagnostic language and psychological tests to assess his ability to perceive and comprehend, and his intellectual potential. Younger children are accepted as patients with the ultimate aim of placing them in a regular school when they are of school age. The Institute tends to get the most difficult cases -- those frequently turned away as being too difficult for other institutions to manage.

The philosophy of the Institute is that each child must be studied as an individual and therapeutic devices selected and designed for him. Even the diagnostic aspects often need to be adapted in the light of the child's limitations to receive and produce language symbols.

In some cases this is done with games where a child learns to identify objects or pictures with words. In other cases spoken language is initially bypassed and the child is taught to respond to visual materials as a basis for appreciating the relationship between pictures and language symbols. Some of these children are in fact taught the beginnings of reading before they begin to use conventional spoken language.

After communication of some sort is securely established with a child, clinicians may then proceed to teach him to discriminate between sounds and eventually to speak and understand conventional language.

Since the Institute was established, more than 80 children have been evaluated. At present 15 are seen daily by staff clinicians, and others have been given suggestions for treatment by their own doctors or schools. Of those treated to date by the Institute, five have been "discharged" to special or regular classes in public schools.

In addition to Dr. Eisenson, staff members at the Institute are: Dr. Joel Stark, postdoctoral fellow; Mrs. Silvia Cohen, psychologist; Robert Gottsleben, senior clinician; Carol Foster, clinician; Mrs. Jane Gidden, junior clinician; and Mrs. Lilian Clark and Mrs. Maxine Carlson, secretaries. Dr. Thomas Forest is the Institute's representative of the Department of Pediatrics and acts as liaison with the medical faculty.

A new system of obtaining eyes for corneal transplants has been instituted at the Stanford Medical Center.

Called "Eye Alert," it will revolutionize present eye banks, according to Dr. Frank C. Winter, acting head of the Division of Ophthalmology. "Eye Alert" makes it possible to obtain eyes where they are needed and when they are needed.

It works this way: The admitting office, nursing office and emergency room at the Center are alerted to notify the ophthalmologist on duty when a patient dies. If the eyes are in good condition, the ophthalmologist immediately gets in touch with the patient's family and secures permission to use the eyes in transplant surgery. So far, more than half of the families have responded favorably. Usable eyes are available within two days at the most after "Eye Alert" is put into effect.

"Eye Alert" has three main advantages over the present eye banks, Dr. Winter said: fresher corneas are available, a patient doesn't have to wait two or three weeks for his transplant operation, and the procedure is much less expensive. Fresh corneas -- no more than 24 hours old -- are vital to the success of an eye transplant.

Eye banks have provided an invaluable service, Dr. Winter said, but there is no way of knowing when donor eyes will be available, how long it will take to transport them to the Center, and whether they will be usable when they arrive. Eyes have been sent to the Center from as far away as Boston and some of them have not been usable. Corneas cannot be used if they came from persons who had venereal diseases, diseases of the liver, cancer, long periods of weakness or debility, high fevers, burns, or various virus conditions.

So far, more than a dozen successful transplants have been performed at the Center under "Eye Alert" on patients who have come from as far away as Alaska and Peru.

RESEARCH CENTER FOR PREMATURE INFANTS WILL BE FEATURED ON KQED

The life of a premature baby -- a fragile, vulnerable and totally dependent morsel of humanity -- will be explored on Science Reporter Thursday, March 12 at 4:30 and 10 p.m. on KQED-TV (Channel 9) in San Francisco.

Host John Fitch will take television viewers on a rare tour of Stanford Medical Center's research facility for prematurely born babies.

Featured on the half-hour program will be Dr. Norman Kretchmer, executive head of the Department of Pediatrics of Stanford University School of Medicine, and Dr. Philip Sunshine, assistant director of the Research Center for Premature Infants.

They will discuss the purpose of the Center and what basic knowledge investigators hope to glean that can be applied in the saving, care, and feeding of premature babies everywhere.

The Research Center for Premature Infants was opened at Stanford a year ago. It is the first such center established by the National Institutes of Health for the intensive investigation of prematurely born babies.

One of the many peaceful facets of the nuclear age -- the application of its knowledge and products in the field of medicine -- will be demonstrated in the Stanford Medical Center's exhibit, "A Glimpse at Nuclear Medicine," at the second annual Santa Clara County Health Festival, April 3 through 5.

The festival, sponsored by the San Jose Junior Chamber of Commerce, will be in the County Fairgrounds Pavilion in San Jose.

Stanford's exhibit will describe some of the latest developments which have made possible the use of radioactive isotopes in diagnosis and treatment of disease.

These include improvement of radiation detection equipment, development of radioactive substances that concentrate in particular organs and tissues, and better understanding of the factors necessary to obtain clear pictures that can be interpreted by the physician.

The display will show how radioisotopes are used at Stanford Medical Center to diagnose diseases of the brain, liver, kidney, heart, thyroid, spleen, pancreas, bone and lung; also how these radioactive substances are used to destroy certain cancers, to study the cardiovascular system, circulation of the blood, and to measure body fluids, and as tracers in the study of metabolism.

Another part of the exhibit will emphasize the instruments and methods used to obtain pictures of an organ of the body in which radioactive material has been injected, as well as the precautions taken to eliminate the hazards of patient and personnel exposure to harmful radiation.

Nearly 60 exhibits have been entered at the festival by hospitals and health organizations in Santa Clara County. The festival's goal is to make residents more aware of health problems and to show them all the institutions to which they can turn for help.

Admission to the festival will be free.

FOR RELEASE MONDAY, APRIL 14, 1964

CHICAGO--A versatile new method for studying the chemical composition of the cells with an intense beam of "laser" light was reported today by researchers from Stanford Medical Center in Palo Alto.

It is an important new application of the laser, an optical device that produces pencil-thin beams of light of immensely high energy.

Dr. Robert C. Rosan, assistant professor of pathology, and Dr. David Glick, head of the division of histochemistry at Stanford University School of Medicine, described the laser's newest application at the 48th annual meeting of the Federation of American Societies for Experimental Biology.

In essence, the intense energy from a laser beam is focused through a microscope on a spot of tissue about two hundredths of an inch in diameter. The tissue is vaporized by the laser at a temperature of 18,000 degrees in about 10 billionths of a second. The vapor is passed into an electric arc and each element in the vapor yields a characteristic spectrum of lines that can be recorded on film.

The lines represent not only each chemical element's "fingerprint" but their intensities may give an estimate of the amount of the element in the tissue, the investigators reported.

The new method was described "as simple and rapid, permitting simultaneous analysis of 10 or more elements in any tissue." The entire procedure takes less than a second and requires very small tissue samples (about one thirty billionth of an ounce). The very small spot of tissue needed permits the analysis to be applied to a few cells of a given type.

- more -

The same analysis, done with conventional test-tube methods, would require 20 to 30 minutes for every single element, the researchers emphasized.

The type of equipment used in the Stanford experiments was the Laser Microprobe with a conventional spectrographic device. It was developed by Frederick Brech of the Jarell-Ash Company at Waltham, Mass. It uses a "ruby laser" in which the beam is produced by exposing a synthetic ruby rod to an intense flash of light.

The two researchers have already applied the new technique in the study of the calcium, iron, cobalt, and zinc, among other elements, in adrenal glands, kidneys, and teeth. They have also applied it to living animals and one volunteer researcher without harm, thus obtaining a direct analysis of skin, tooth, and hair.

Dr. Rosan and Dr. Glick plan to use the laser device to study the effect of the adrenal gland on the distribution of salts and metal in body fluids. These fluids are important in such conditions as stress, cardiovascular disease, and stomach ulcers.

Another area of future investigation is a children's disease known as cystic fibrosis of the pancreas. In this disease, the secretions of the intestine become too thick for normal function, and too much salt is secreted when the child perspires.

The new laser device could be used to find out why the sweat of these children has so much salt, the researchers said.

# # #

(Mailed April 10, 1964)

A new important application of the laser to the study of the chemical composition of the cells has been reported by researchers from Stanford Medical Center. By using the pencil-thin beams of light of immensely high energy from a laser, the Stanford researchers have been able to conduct simultaneous analysis of 10 or more elements in any tissue, including tissue of living animals. The entire process takes less than a second. The device used in the experiments consists of a laser, microscope and spectrograph. Pictured here with the laser is Dr. Robert C. Rosan, assistant professor of pathology, and Miss Mollie Settle, research assistant.

Dr. Alvin J. Cox, executive head of the Department of Pathology at Stanford University School of Medicine, has asked to be relieved of his administrative responsibilities, Dean Robert H. Alway said today.

Dr. Cox will join the Department of Dermatology as professor of pathology and will devote himself to expanded research activities in skin pathology, particularly as it relates to psoriasis. His new appointment will be effective September 1.

He is noted for his pioneer studies in the fields of stomach pathology, chronic poisoning, and experimental cancer.

Dr. Cox, an alumnus of Stanford University School of Medicine, joined the Medical School faculty in 1931. He served as executive head of the Department of Pathology for the past 23 years. Dr. Cox played a key role as chairman of a 22-man faculty committee which evaluated long-term objectives of Stanford medical teaching, and recommended a new curriculum adopted in 1959.

EDITORS: This story transmitted on Business Wire 4/30/64.

Dr. LeRoy E. Bates, 41, has been appointed executive vice president and director of the Palo Alto-Stanford Hospital, its board of directors announced Thursday.

Dr. Bates, currently director of the Union Memorial Hospital in Baltimore, Md., will assume his new duties in July. He will fill the post vacated by Oliver E. Deehan who resigned as administrator in January.

Gordon P. Smith, president of the board, said that "the Palo Alto-Stanford Hospital is most fortunate to attract as administrator a person of Dr. Bates' knowledge, ability, and professional experience."

Selection of the new administrator was made after a nationwide search by the board.

Dr. Bates was born in Charleston, S. C. He received his Bachelor of Science degree from the College of Charleston, his medical degree from the Medical College of South Carolina, and a Master of Public Health degree from the School of Public Health of the University of California at Berkeley.

Previously, Dr. Bates served as a medical officer with the U.S. Public Health Service and the World Health Organization, and did research in tuberculosis in India, Denmark and Egypt.

Before joining the Union Memorial Hospital, Dr. Bates held positions as secretary of the Council on Professional Practice and assistant director of the American Hospital Association in Chicago, and as assistant director in charge of outpatient services at Johns Hopkins Hospital in Baltimore.

He and his wife Judith have 6 children. She is formerly of Bakersville, Calif.

The John A. Hartford Foundation of New York has made a three-year grant of $318,590 to the Stanford University School of Medicine to continue its intensive studies of diseases of hereditary and developmental origin, it was announced today by Ralph W. Burger, president of the Foundation.

The studies were launched at Stanford in 1960 with an initial Hartford Foundation grant of $395,028. They are under the direction of the Department of Pediatrics.

Purpose of the multi-discipline investigations is to obtain information useful in the understanding and treatment of hereditary diseases whose cause and cure are unknown.

Crippling diseases affecting bones and connective tissues, intestinal disorders, congenital heart defects, blood disorders, neuromuscular diseases as well as some aspects of mental retardation will be studied in children and laboratory animals.

In addition, studies will be conducted to evaluate the effect of certain drugs and vitamins on the development of the unborn offspring. The tragic affects of the drug Thalidomide administered to pregnant women are now well-known. But there are other drugs which may affect infants in terms of their anatomical and biochemical development.

Dr. Norman Kretchmer, professor of pediatrics and executive head of the department at Stanford, is the principal investigator. He is assisted by several other faculty members including Dr. William van B. Robertson, Dr. Luigi Luzzatti, Dr. Herbert Schwartz, Dr. Kenneth K. Tsuboi, Dr. Paul H. Altrocchi, Dr. Guy M. McKhann, Dr. Robert E. Greenberg, Dr. Irwin A. Schafer, and Dr. Norman J. Sissman.

- more -

"The generous Hartford grant will strengthen further our committment to the study of growth and development," Dr. Kretchmer said. "We feel more strongly than ever that this approach offers the possibility of a maximum contribution to child health."

The proposed studies in the next three years will focus on problems of food digestion and absorption using animals as models for sick babies.

Body processes of breaking down complex foods into simple ones and synthesizing them into complex tissues differ in early life from those of the mature individual, Dr. Kretchmer explained. Abnormalities in these processes in some children lead to serious difficulties in later life.

For example, some of the muscular dystrophies are associated with a loss of potassium and can be treated simply. Most diseases of the blood in children involve abnormal production of hemoglobin, the substance within the red cells which transports oxygen to the lungs. Many of the diarrheas in infants are associated with their inability to digest and utilize carbohydrates and fats.

Dr. Kretchmer hopes that findings from this work will also be applicable to premature babies. About eight per cent of all babies born in America are born too soon. These babies are different in chemistry from normal full-term babies. They show intolerance to fats and have different protein needs.

Because they are so different they can't even handle the favorable, controlled environment of a nursery. Many of these babies die of respiratory problems or infection.

"We want to know what a premature baby is in terms of its biochemical development," Dr. Kretchmer said. "This way we can give these babies optimal care and, hopefully, increase their survival chances."

A study of sea lion pups that may lead to development of satisfactory formulas for babies suffering from severe diarrhea was reported today by two Stanford Medical School physicians.

The physicians are Dr. Philip Sunshine, instructor in pediatrics, and Dr. Norman Kretchmer, executive head of the Department of Pediatrics. Their report appears in the current issue of SCIENCE.

For the past year the two pediatricians studied pups of California and Stellar sea lions and found that these two species have no intestinal enzymes necessary to digest and utilize lactose, the sugar which is present in milk.

"If these animals were given lactose, they developed severe diarrhea followed by loss of weight," the two physicians reported. "These symptoms were identical to those found in human babies who could not tolerate milk sugar."

No mammal had been found without lactose in its milk until a year ago. Two researchers from the Scripps Institution of Oceanography of the University of California at San Diego reported that the milk of the California sea lion does not contain the common sugar.

Further reports from the San Diego Zoo Hospital and Laboratory showed that all attempts to feed infant sea lions or walruses with cow's milk met with disaster; these animals developed severe diarrhea.

The Stanford pediatricians have been working on the problem of lactose metabolism by infant animals as part of a large-scale investigation of diseases of hereditary and developmental origin, with support from the John A. Hartford Foundation of New York.

- more -

Hoping that by studying sea lion pups they would find a method of treating sick babies with this specific diarrhea, a team consisting of Dr. Kretchmer, Dr. Sunshine, Dr. William van Robertson, Dr. Kenneth Tsuboi, and Dr. Robert E. Greenberg last summer sailed on a 70-foot vessel of the Scripps Institution of Oceanography to the Coronado Islands off the coast of Mexico.

On reaching the islands they found many sea lion pups in a rocky cove basking in the sun. They captured three pups between one and two months of age and weighing from 19 to 30 pounds.

At the San Diego Zoo, the pups were placed in a cage equipped with a pool. Since the pups had been taken from their mothers before natural weaning, an attempt was made to simulate sea lion milk using several types of sugar-free basic diets together with vitamin supplements. Later the animals were flown to Stanford Medical Center and placed under the supervision of the Animal Care Facility.

As the pups refused solid food and rejected any attempts to be fed with a bottle and nipple, a stomach tube had to be passed three times a day to maintain adequate nutrition. The investigators added various sugars to this synthetic diet and observed physiological and biochemical changes.

Dr. Kretchmer and Dr. Sunshine concluded that pups of the California and Stellar sea lions can be used as models for studying sick human infants with hereditary intolerance to some sugars.

With this knowledge they hope to develop satisfactory formulas for feeding infants who have difficulty digesting and absorbing the sugar found in milk.

A Stanford biochemist whose research has contributed toward understanding and ultimate control of heredity was honored last night as California Scientist of the Year.

Dr. Paul Berg, 38, professor of biochemistry at Stanford University School of Medicine, received his award from the California Museum of Science and Industry at Los Angeles at a banquet in the Beverly-Hilton Hotel.

Dr. Berg received an award of $5,000. Presentation was made by Dr. Arthur Kornberg, Stanford Nobel laureate and a member of the jury that selected the science category winner.

Honored also was Charles B. "Tex" Thornton, 50, of Los Angeles, board chairman of Litton Industries, Inc. He was named California Industrialist of the Year for his contribution to the State's economic and cultural development.

Dr. Berg is the third Stanford professor to win the prestigious award and the first biochemist. The other two are Dr. Robert Hofstadter and Dr. William M. Fairbank, both professors of physics.

Dr. Berg was selected for his accomplishment in work concerned with decoding the genetic messages or patterns which determine how living cells make proteins.

- more -

As more and more diseases have been shown to result from defective genes or aberrations in this translation process, it is believed that some forms of cancer might ultimately be explained in terms of such individual genetic patterns.

A full understanding of this process as sought by Dr. Berg and his research team, is felt to be essential for eventual prevention, treatment and hopefully cure of such hereditary diseases.

A native of Brooklyn, New York, Dr. Berg is the son of a Russian immigrant who became a fur manufacturer in New York City. His first interest in science sprang from experiments he performed as member of a Brooklyn high school science club.

Dr. Berg obtained his B. S. degree from Pennsylvania State College, his doctorate from Western Reserve University, and his postdoctoral training at the Institute of Cytophysiology in Copenhagen and at Washington University at St. Louis, Mo.

The awards are sponsored annually by the California Museum of Science and Industry in Los Angeles and its educational affiliate the California Museum Foundation, to provide public recognition to individuals who have made the most noteworthy contribution to the advancement of knowledge and the development of the State's economy.

FOR RELEASE WEDNESDAY, MAY 6, 1964

Dr. William C. Dement, 35, associate professor of psychiatry at Stanford University School of Medicine, has received the $1,500 Hofheimer Prize for outstanding research accomplishment in psychiatry.

Announcement of the award was made by the American Psychiatric Association holding its 120th annual meeting in Los Angeles.

Dr. Dement was awarded the prize for his work on the nature and function of sleep and dreaming, a line of research he has pursued since he was a medical student at the University of Chicago. In 1953 he began his work there in the physiological laboratory of Prof. Nathaniel Kleitman who confirmed the occurrence of rapid eye movements during sleep.

Dr. Dement participated in these studies and received his Ph.D. in physiology in 1957. He then began to work independently, chiefly as a Research Fellow at Mt. Sinai Hospital in New York from 1958 to 1962, and since 1963 at Stanford.

After further research to confirm and evaluate the relationship of dreaming to the presence of rapid eye movements during sleep, he explored many other aspects of sleep physiology. He established that rapid eye movements occurred in discrete periods during sleep and that these movements are associated with other characteristic physiological changes.

From these studies Dr. Dement formulated the concept of "two kinds of sleep." One kind is the rapid eye movement or dreaming period, which shows intense activation of the central nervous system and other attributes which contrast it paradoxically with the common notion of the nature of sleep.

- more -

His work made it possible to study a number of properties of dreaming, such as the time of occurrence and the number of dream periods. He found that in humans, dreaming occurs nightly approximately four to six times for 20-minute periods each, and that dreaming occupies about 20 per cent of total sleeping time.

Dr. Dement also studied cats and found similarities -- rapid eye movements and "two kinds of sleep." The use of cats made it possible to carry out studies of a more experimental type on the physiological basis of dreaming.

More recently, Dr. Dement and his associates have attempted to study the function of dreaming sleep by depriving human and animal subjects of this phase of sleep. They have a hunch that the rapid eye movement or dreaming sleep may be necessary and vital for human beings. The study may shed light on the role of loss of dreaming sleep, through a number of possible mechanisms, in the development of mental illness.

Dr. Dement was born in Walla Walla, Washington. He received his B.S. degree at the University of Washington in 1951. After graduation from medical school in 1955 he was granted a U.S. Public Health Service Postdoctoral Fellowship, and a Foundations' Fund for Research in Psychiatry Fellowship in 1958. He is married and has three children.

The APA award is named in memory of Lieut. Lester N. Hofheimer who died in action in World War II and may be given annually to a research worker or group. The Hofheimer Prize Board selected this year's winner from 35 applications.

A study showing significant gains in the treatment of larynx cancer by X-Ray therapy was reported Tuesday at the American Medical Association convention in San Francisco.

Three Stanford Medical School physicians said they were treating the disease with large doses of radiation from a medical linear accelerator, with an X-Ray beam having a peak energy of about six million electron volts.

The physicians were Dr. Malcolm A. Bagshaw, associate professor of radiology, Dr. Michel Schlienger, visiting radiotherapist from the Curie Foundation in Paris, and Dr. Henry S. Kaplan, executive head of the department of radiology.

"The overall results in treatment of larynx cancer confined to the vocal cord were excellent," the physicians said.

Of 51 patients admitted to the Stanford Medical Center, 45 were successfully treated by radiation and four patients had laryngectomies after failure of radiation therapy. The patients who were treated by radiation have retained full use of their voice. Only two patients were not cured of the disease.

"Thus the outlook for survival is virtually 100 per cent and survival with preservation of the voice nearly 90 per cent," the doctors said.

The average radiation dose used by the Stanford team was 6000 rads in six weeks -- considerably higher from conventional standards.

- more -

Cancer of the larynx occurs in approximately two per cent of the population. Its cause is unknown, although it occurs somewhat more frequently among heavy smokers.

Unlike cancers which can be seen, cancer of the voice box cannot be felt without a special examination. But it does give a sign of its presence which can be heard. The sign is hoarseness. Fortunately, in most cases this warning note is sounded early in the development of the growth. The high rate of curability makes early diagnosis of unquestionable value.

The Stanford physicians, in somewhat less optimistic tone, noted that "there is room for improvement in the cure rates of patients with more advanced cancers of the larynx which are not confined to the vocal cord. These remain an unsolved problem to the radiotherapist as well as to the surgeon and should be explored."

They pointed out that patients were treated successfully by surgery after radiation therapy failed. But they added, "Successful irradiation of patients who have local recurrence following laryngectomy is virtually impossible."

FOR PM RELEASE, WEDNESDAY, JUNE 24, 1964

Note to Editors: This paper will be presented Wednesday at 2 p.m. in the Van Ness Masonic Temple, third floor auditorium.

A new method of detecting and treating rejection of transplanted kidneys has kept dogs alive for more than 75 days, a Stanford Medical School research team reported today.

The technique enables doctors to predict when the rejection of the grafted or borrowed organ will begin and provides a reliable guide for controlling the dosage of immunosuppressive drugs.

Authors of the report were Dr. Samuel L. Kountz, Dr. Donald R. Laub, residents in surgery, and Dr. Roy Cohn, professor of surgery. They presented their findings at the annual convention of the American Medical Association in San Francisco.

"Animals treated by the new method," the researchers said, "had longer survivals, very little toxicity, and infections responded well to antibiotic treatment."

Monitoring of the rejection process and the effectiveness of immunosuppressive drugs has been one of the major obstacles in the practical transplantation of organs.

Before the method was developed, the average survival rate of dogs with borrowed kidneys was 40 days. More than 40 per cent of them died from overdosage of the immunosuppressive drugs while the transplanted kidney was still functioning.

- more -

The researchers explained that the technique enables them to obtain measurements of the kidney blood supply during the functional period of the graft in the experimental animals. Comparing simultaneously their new techniques to other currently used methods, they found that a fall in blood flow was the first detectable signal that the rejection mechanism was taking place.

At this point they can inject drugs which suppress the rejection mechanism by restoring the blood flow. Then the successive threatened rejections "come on slower and are easier to handle," the doctors said.

Present plans at Stanford are to continue to refine the approach to the use of these drugs through animal experiments in order to pinpoint which drugs, how much of them, and when they should be given for saving the graft.

The investigators said: "If the solution of the clinical problem in kidney transplantation resides in immunosuppressive drug therapy rather than a biological maneuver to induce specific tolerance, then considerably more information must be obtained as to specific drugs, their dosage, and optimal time of administration."

The idea for the new technique was inspired mainly by a discovery reported by Dr. Kountz at the American College of Cardiology earlier this year and for which he was honored as "outstanding young investigator of 1964."

Dr. Kountz who spent a year in the Medical School of London as a Bank of America-Giannini Fellow in surgery, showed that the rejection mechanism was operating at the level of cells.

When a kidney was transplanted from one dog to another, he and his associates watched the canine patients carefully expecting the blood supply to become normal. Instead, there was a gradual but constant decline in the blood supply.

Looking for a reason, Dr. Kountz put kidney tissue under an electron microscope, and was able to spot the cause -- immature plasma cells from the blood of the host animal.

These immature blood cells had closed in and attacked the cells lining the small blood vessels of the grafted kidney. After contact, the lining cells appeared to curl up and become isolated. Soon the blood vessels of the kidney were blocked by a mass of blood cells, chocking off the blood supply.

From there on the kidney died from lack of blood-supplied oxygen.

Now, with the newest pinpoint use of immunosuppressive drugs, rejection in the kidney in its early stages can be temporarily reversed.

# # #

(Mailed June 22 , 1964)

Dr. Samuel L. Kountz (left) and Dr. Donald R. Laub of Stanford Medical Center, view the successful results of a kidney transplant operation they performed on two dogs last September. The dogs are alive because of a new method developed by Dr. Kountz and his associates. It enables them to predict when the rejection of the borrowed organ will begin and provides a more accurate way of controlling the dosage of immunosuppresive drugs.

A Stanford professor and nationally known expert on childhood aphasia has been named a "Captain of Achievement" by the American Academy of Achievement at Oceanside, Calif.

Dr. Jon Eisenson, professor of speech pathology and audiology at Stanford University School of Medicine, will receive individual recognition at a banquet at Camp Pendleton June 27.

Dr. Eisenson will receive the achievement award for his work as director and founder of the Stanford Medical Center's Institute for Childhood Aphasia. Aphasia is caused by brain damage which impairs a child's ability to speak and often to comprehend written and spoken language. The Institute, supported by a continuing grant from the California Scottish Rite Foundation, has made it possible for Dr. Eisenson and his staff to experiment and develop techniques and procedures for diagnosis and treatment of aphasic language disorders in children.

The American Academy of Achievement is a nonprofit organization founded for the purpose of honoring annually Americans who have made outstanding contributions to the sciences, the arts, the professions, business, education and public service.

In addition to his duties at Stanford, Dr. Eisenson is chairman of the education, advisory and research committee of the United Cerebral Palsy Association, and a member of its medical and scientific committee.

Two books he has written, related to his specialty, have been published within the past year -- PSYCHOLOGY OF COMMUNICATIONS and BASIC SPEECH.

FOR IMMEDIATE RELEASE

STANFORD - Lowell Patrick Wilson, 19, of 1230 Manu-mele St., Kailua, Hawaii, will register for summer school at Stanford on Monday (JUNE 22).

What makes Lowell P. Wilson different from the other 3600 summer students at Stanford is that he is paralyzed--probably permanently--from the neck down. He broke his spine in a dummy-tackling accident during spring football practice May 2, 1963.

From here on out, Lowell's physical world will be bounded by a rocking bed to supplement his breathing, a motorized wheel chair to get around in, and round-the-clock care by male nurses.

But nevertheless, he will attend a class in Shakespeare.

His mental world is something else again. A strong-minded optimist, Lowell still doesn't think of himself as a cripple.

At the time of his accident, Lowell's injuries were so severe he might have died on the field had not ambulance service been available immediately.

Through the joint efforts of the Student Health Service, rehabilitation services, and 11 other services at Palo Alto-Stanford Hospital, Lowell can now move his head and neck and breathe without help.

He has taught himself to type, using a rubber-tipped stick. Rolling his head to and fro operates a page-turner for reading books and switches on and off a tape recorder for dictation.

Lowell's injury, which fractured his spine between the fourth and fifth vertebrae in his neck, destroyed his breathing capacity in addition to paralyzing all muscular activity below his neck.

Dr. Allen Russell, a fellow in the Division of Rehabilitation Medicine at the Stanford Medical School, supervised Lowell's manful comeback efforts.

Dr. Russell points out that patients with fractures in this area generally succumb to breathing difficulties either from muscle failure or from respiratory illnesses.

(more)

6/21/64

The combined efforts of the hospital's intensive care unit, the respiratory unit, and rehabilitation staffs brought Lowell to the point where after 13½ months, he no longer needs continuous mechanical assistance from a respirator machine to breathe.

He now supplements his own slight breathing capacity with a method of swallowing air and by regular periods in a rocking bed, which has been set up in a former faculty resident's house attached to Wilbur Hall, freshman dormitory.

The bed pushes and pulls his abdominal organs against his diaphragm to move air in and out of his lungs.

Two student aides will maintain the physical therapy which keeps his joints movable and his muscles toned up.

"Physicians expect no further improvement in his physical condition," Dr. Russell says, "but Lowell will become more independent as he learns to use new devices such as an electric wheel chair and dictating devices."

So Lowell Wilson of Kailua, Hawaii, has brought himself back toward recovery with his fighting heart and the help of medical science.

When he came to Stanford in the fall of 1962, Lowell was an outstanding guard on the frosh football team. He was making a strong bid for a lineman's spot on the '63 varsity when fate decreed a one-in-a-million accident.

As a prep star at Kamehameha School, he was an all-state footballer, vice-president of the student body, editor of the school paper, active in debate and dramatics, a chess buff, and a Sunday School teacher.

When he registered at Stanford, it was on a straight academic scholarship with a political science major as a basis for Law School.

The University will support Lowell's efforts to continue his education at Stanford, including necessary equipment, living expenses, and tuition, for a reasonable period as long as he is able to maintain a satisfactory level of academic performance.

If young Wilson has anything to say about it, he'll make it.

FOR RELEASE TUESDAY, JUNE 23, 1964

Investigators at Stanford University School of Medicine and the Palo Alto Medical Research Foundation have used a laser photocoagulator to treat 25 patients with a variety of retinal diseases.

Reporting these results today at the annual convention of the American Medical Association in San Francisco, Dr. Milton Flocks and Dr. H. Christian Zweng said:

"Laser energy has been used for photocoagulation of ocular tissues in animals and man. It has unique properties which promise to extend its usefulness. It is still, however, in the experimental stage."

Dr. Flocks and Dr. Zweng are practicing ophthalmologists in Palo Alto. They carried on the research work with the laser photocoagulator under U.S. Public Health Service grants to the Palo Alto Medical Research Foundation and Stanford University School of Medicine. Both physicians are Foundation research associates and members of the clinical faculty at Stanford Medical School.

The investigators used an experimental laser coagulator developed in association with Dr. Narinder S. Kapany, Norman Peppers and Norman Silbertrust of Optics Technology, Inc., at Belmont, Calif. The device consists of an ophthalmoscope with a hand-held ruby laser which fires powerful bursts of light of short duration (500 microseconds).

When aimed at the eye, the intense laser light will pass through transparent tissue and liquid and can be used to treat retinal defects.

- more -

The light beam has been particularly effective for prevention of retinal detachment. In cases in which holes or tears appear in the retina they can be "spot welded" back in place by the light beam before a retinal detachment takes place.

Before its application on humans, the laser coagulator had been extensively tested on rabbits, cats and monkeys in the Stanford Division of Ophthalmology, the physicians said.

Of the patients treated, 23 had retinal photocoagulation and two had iris photocoagulation. All but one patient were treated as outpatients. Except for heavy work they were allowed to resume normal activities after treatment.

The patients directed their gaze in the position which offered the ophthalmologist the best view of the area to be treated. The area was then treated with multiple exposures to the laser. No anesthesia was needed. The eyes were not patched after treatment.

"The patients experienced remarkably little discomfort," the investigators said. "The flash of light occurred so rapidly they were hardly aware of it. Some stated they were bothered by the slight 'popping' noise of the laser burst more than the light."

The physicians reported that in the patients who have been treated no major complications have been encountered during the past nine months. However, they added, "the patients are too few, and the follow-up too short to be certain that laser coagulation will prove to be good enough to be used in preference to other modes of therapy."

# # #

(Mailed June 18, 1964)

Dr. Milton Flocks, Palo Alto ophthalmologist and member of the clinical faculty at Stanford Medical School, prepares to begin laser photocoagulation treatment on a patient. Dr. Flocks and Dr. H. Christian Zweng, also a Palo Alto ophthalmologist, told the American Medical Association convention in San Francisco that laser energy used for treatment of retinal diseases has unique properties which promise to extend its usefulness.

Dr. Sidney Raffel, 52, executive head of the Department of Microbiology, has been appointed acting dean of the Stanford University School of Medicine, acting president Frederick E. Terman announced today. His appointment is effective ~~immediately~~. July 15, 1964

Dr. Raffel will replace Dean Robert H. Alway who asked to be relieved of his administrative duties last December. Dr. Raffel will remain in his new capacity until a new dean is selected.

Dr. Raffel is noted for his research in immunology, specifically for work on tuberculosis and allergic disease. He has also contributed to developments in the use of X-ray in tissue grafting and transplantation.

He is the author of a textbook entitled IMMUNITY and has written numerous papers and pamphlets. He is a member of various honorary and professional societies, was a Guggenheim Fellow in 1950-51, and he has served on committees of the National Institutes of Health, the National Tuberculosis Association and as editor of various professional journals.

Dr. Raffel is a graduate of Johns Hopkins University where he also received his doctorate in science. He earned his medical degree from Stanford University School of Medicine and has been a member of the Stanford University faculty for 29 years.

He and his wife reside at 770 Santa Ynez, Stanford. They are the parents of five daughters.

FOR PM RELEASE, MONDAY, JUNE 22, 1964

The hazards of collecting and eating wild mushrooms were detailed today by four Stanford physicians at the annual convention of the American Medical Association in San Francisco.

Dr. Donald C. Harrison, Dr. Cecil H. Coggins, Dr. Frederick H. Welland and Dr. Sherwin Nelson described the effects of mushroom poisoning in five patients treated in the Palo Alto-Stanford Hospital earlier this year.

At first, the victims suffered from nausea, vomiting, abdominal pain and diarrhea, sometimes resembling cholera in severity, the doctors reported. After a period of apparent improvement, the patients began to show signs of liver, kidney, and central nervous system damage, with life threatening consequences.

Evidence of the effects of the mushroom poison on the patients' nervous system included confusion, coma, visual disturbances and abnormal reflexes, the doctors said.

The patients -- two men and three women -- had gathered and eaten mushrooms of the *Amanita verna* and *Amanita phalloides* families. Both species grow in abundance in the San Francisco Bay Area after the fall rains and through the winter and spring.

Four of the victims have subsequently recovered. One patient died from severe liver and kidney damage, the doctors reported.

- more -

"Although we have described three distinct phases in the clinical course of mushroom poisoning," the physicians said, "all may blend into a single picture of vital liver and kidney cell destruction with death occurring at any time in more severe cases."

The physicians noted that there is no specific therapy for mushroom poisoning. The use of antiphalloidin antiserum and cortisone in the treatment of patients has not gained widespread acceptance. "In the absence of specific treatment careful supportive therapy is all that can be offered," they said.

The species Amanita phalloides, Amanita muscaria and Amanita verna are among the leading causes of mushroom poisoning in the United States, according to the Stanford physicians.

"Amateur mycologists in recent articles in national magazines have given the impression that wild mushrooms can be casually gathered and safely eaten," they said. "It is generally recognized by botanists that while some species may easily be identified, many harmless mushrooms can be distinguished from the Amanita varieties only with difficulty."

Complicating further the problem of identification is the fact that the toxin content within various species of mushrooms may vary widely with the seasons, environment, and age of the mushrooms.

"The mushroom which is harmless at one time and place might be lethal at another," the doctors said.

Palo Alto, California

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos (DA 1-5310)

NOTE TO EDITORS: Story was relayed by phone June 6, 1964.

Dr. Lowell A. Rantz, professor of medicine at Stanford University School of Medicine and noted authority on bacterial diseases and their treatment, died Friday in Boston where he was attending a medical meeting. He was 52.

With Dr. Rantz at the time was Dr. Kenneth L. Vosti, assistant professor of medicine at Stanford Medical School.

Dr. Rantz suffered a heart attack and was dead on arrival at Massachusetts Memorial Hospital.

Dr. Robert H. Alway, dean of Stanford Medical School commented: "We have lost a distinguished professor who, as clinician, teacher and researcher, contributed immesurably to furthering the highest aims of the School of Medicine."

Dr. Rantz's roots in Stanford were deep. Born in Placerville, Calif., he received his A.B. degree from Stanford University in 1932, and his medical degree from Stanford Medical School in 1936. After spending two years as a research fellow in medicine at Harvard Thorndike Memorial Laboratory, Dr. Rantz joined Stanford University and grew professionally with it. In 1958 he was appointed associate dean of the School of Medicine.

Much of his research work at Stanford has been concentrated on rheumatic fever. He was one of three doctors who discovered the significant fact that rheumatic fever, one of the nation's great cripplers, is always preceded by hemolytic streptococcal infections.

- more -

Dr. Rantz was a member of many professional and scientific organizations, including the American Association of Physicians, the American Society for Clinical Investigation, and the American Association for the Advancement of Science. He was recently elected president of the Western Association of Physicians.

He also served on many committees of the American and California Heart Associations, and was president of the San Francisco Heart Association from 1950 to 1952.

In Palo Alto Dr. Rantz leaves his immediate family -- his wife Helen, and daughter, Elizabeth -- and many friends and colleagues.

Funeral services will be Tuesday at 2 p.m. at Roller and Hapgood Funeral home, 980 Middlefield Road in Palo Alto. The family requests that instead of flowers, contributions be made to the Lowell A. Rantz Memorial Fund at Stanford University School of Medicine.

Two Stanford Medical School professors will retire this summer after more than 50 years of combined service.

The two are Dr. George S. Johnson, professor of psychiatry, and Dr. William W. Greulich, professor of anatomy. Each in his own field has contributed to a broad scope of activities.

A graduate of the University of Nebraska, Dr. Johnson came to San Francisco in 1933 and became head of the psychiatric services at Stanford Lane Hospital. He served on the board of directors of the Community Chest and was chairman of the San Francisco Health Council. Many existing welfare agencies, including the well-known Family Service Agency, were organized during his tenure.

A concern with human problems led to his appointment by the U.S. attorney general as a consultant to Alcatraz Federal penitentiary. He also served on committees appointed by a succession of state governors to study psychiatric problems in the department of mental hygiene including the committee for the improvement of California's state hospitals.

A five-year grant from the March of Dimes to the Medical School was responsible for an enlarged rehabilitation program for victims of polio and other disabled patients in San Francisco. Dr. Johnson served on the committee which developed the program.

- more -

Dr. Johnson is presently serving on the State Board of Medical Examiners. He resides at 1960 Vallejo Street, San Francisco.

Dr. Greulich's higher education started at Kenyon College, Ohio, with a degree in philosophy, a masters from the University of Denver and a doctorate from Stanford.

His itching feet continued to keep him circulating around the United States with teaching posts at the University of Colorado, Yale University School of Medicine, Western Reserve University and Stanford where he was executive head of the Department of Anatomy. Then to the Orient where he made the first survey and documented the retardations among Japanese children who survived the atom bombs dropped on Hiroshima and Nagasaki. The results of this study made him the winner of the 1960 Viking Fund medal and award for "outstanding achievement in physical anthropology."

In Europe he was science adviser to the U.S. High Commissioner for Germany after World War II. In 1961, he went to England as senior scientific attache for the United States Embassy to the Court of St. James where he now resides as his appointment has been extended until 1966.

As an authority in the fields of anatomy and anthropology, he is a member of numerous societies and has received multiple honors as well as being an author on these subjects.

He is a former resident of Menlo Park.

Editors: Story was transmitted on Business Wire 7/30/64.

An Oroville woman who was dying of kidney disease left the Palo Alto-Stanford Hospital Wednesday after receiving a healthy kidney from her mother in an operation in which a new method was used.

Mrs. Ruth Bell, 22, a victim of chronic kidney failure, received a kidney from her 52-year-old mother, Mrs. Wilma Davis, also of Oroville. The operation was done July 10 and took 15 minutes.

Mrs. Bell was a patient in the new General Clinical Research Center of the Hospital which is supported by the National Institutes of Health.

"I feel very fortunate and grateful for the results of the operation," Mrs. Bell said. "I hope that many unfortunate people will be able to benefit from what is learned from the advanced surgery I have had. Until a month ago I had been told that my condition was hopeless. Now it is impossible to explain my gratitude."

Mrs. Bell will move with her mother to San Jose and will report to the Hospital periodically as an outpatient so that doctors can observe her progress. She said she plans to resume her job as a medical secretary.

Surgeons at the Hospital said that the present state of this operation is highly experimental. The operation can only be done after detailed studies of the biological relationship between donor and recipient and of the various immunological problems.

- more -

"We were justified in conducting this operation," the surgeons said, "because we feel we have devised a method which enables us to treat the patient with lower and safer dosages of the powerful drugs that help prevent the rejection reaction. Higher dosages of these drugs frequently result in severe infection because of the depressing effect on the bacteriological defenses of the body."

When organs are transplanted from one person to another the host or recipient tends to treat the grafted or borrowed organ as a foreign invader and marshals forces to reject it. Monitoring of the rejection process had so far been inadequate and was one of the major obstacles in the practical transplantation of organs.

But last June, at the American Medical Association convention in San Francisco, a Stanford medical research team reported that it had found a reliable method which had given them a better warning of when to inject drugs to suppress the rejection mechanism.

The technique was developed after more than a year of studies on experimental animals by Dr. Samuel Kountz, Dr. Donald R. Laub, residents in surgery, and Dr. Roy Cohn, professor of surgery.

By administering radioactive tracer drugs, the researchers were able to obtain measurements of the kidney blood supply in the grafts between dogs. Comparing simultaneously their results with other currently used methods, they found that a fall in blood flow was the first detectable signal that rejection was taking place.

At this point they injected drugs which suppressed the rejection mechanism by restoring the blood flow. Then the successive threatened rejections came on slower and were easier to handle.

"Animals treated by this method," the researchers reported, "had longer survivals, very little toxicity, and infections responded well to antibiotic treatment."

The Bell-Davis transplant was the first time in which the new method was used on a human patient. It was the second human kidney transplant done in the Palo Alto-Stanford Hospital.

The first was in 1960, when a twin brother donated a kidney to Lenneth Pock of Castro Valley, who still lives. However, a transplant between identical twins -- in which the genes are most nearly alike -- is much simpler than a transplant between others.

Mrs. Bell's physicians said that the new technique has worked better than predicted because there is less genetic disparity between mother and daughter than the canine patients used in the Stanford experiments.

The idea for developing the new technique was inspired by a discovery made by the research team earlier this year.

When a kidney was transplanted from one dog to another, the investigators watched the canine patients carefully,expecting the blood supply to become normal. Instead there was a gradual but constant decline in the blood supply.

Looking for a reason, the investigators put kidney tissue under an electron microscope, and were able to spot the cause -- immature plasma cells from the blood of the host animal.

These immature plasma cells had closed in and attacked the cells lining the small blood vessels of the grafted kidney. After contact the lining cells appeared to curl up and become isolated. Soon the blood vessels of the kidney were blocked by a mass of blood cells, choking off blood supply.

From then on the kidney died from lack of blood-supplied oxygen. The newest pinpoint use of immunosuppressive drugs has shown that rejection in the kidney in its early stages can be reversed.

Present plans at Stanford are to continue to refine the approach to the use of these drugs through animal experiments, and to develop a method of selecting genetically compatible donors.

(Mailed July 31, 1964)

Mrs. Ruth Bell, 22, of Oroville, and her 52-year-old mother, Mrs. Wilma Davis, also of Oroville, left the Palo Alto-Stanford Hospital Wednesday. They were met at the Hospital entrance by Mrs. Bell's four-year-old daughter, Kathryn. Mrs. Bell who suffered from chronic kidney failure received a healthy kidney from her mother July 10, in an operation in which a new method was used. Developed at Stanford it enables doctors to monitor the rejection of the grafted organ, and to treat the patient with lower and safer dosages of the powerful drugs that help to prevent the rejection reaction.

Changes in the visiting hours of the Palo Alto-Stanford Hospital were approved Tuesday by the Hospital board of directors.

The changes will become effective January 1 and will replace the present policy of open visiting hours. The Hospital board said limitations in visiting hours were necessary for the care and comfort of Hospital patients.

New visiting hours for patients will be from 2 to 4 p.m. and from 7 to 8:30 p.m. throughout the week. There are a few exceptions:

Children may be visited by their parents at any time unless otherwise directed by their physician. Maternity patients may be visited from 3 to 4:30 p.m. and from 7 to 8:30 p.m. Newborn babies will be shown during the same period.

Other exceptions include patients who are in the intensive care unit, and patients on the day of surgery. Relatives may visit these patients at any time, with permission from the physician or the head nurse.

No more than two visitors for each patient will be permitted in the room.

"Visitors provide a welcome diversion to patients," the board said. "But we rely on the good judgment of our visitors to keep their visits short and reasonably spaced. Most people when they are sick, enjoy company for a short while during the day, no more than 20 minutes. We must request visitors cooperation when asked by a nurse to leave the room, if there is a treatment to be done, or the patient seems to be very tired."

Childless women whose "biologic clocks" have stopped are able to have babies after receiving hormone injections, according to Dr. Emmet J. Lamb, assistant professor of obstetrics and gynecology at Stanford University School of Medicine.

Dr. Lamb is the director of the Infertility and Gynecologic Endocrinology Clinic at Stanford Medical Center where an extensive study of infertility in women is being conducted.

The treatment given by Dr. Lamb and his associates, is specifically for women who have not ovulated, or menstruated, for several years. After tests have proved that there are no organic disorders of the hormone producing glands, the lack of ovulation can then be attributed to a disorder of cycling mechanism of the hypothalamus. This is the part of the brain, or the "biologic clock" which regulates the release of the stimulating hormones secreted by the pituitary gland.

Artificial stimulation of the ovary is induced by injections of the drug Pergonal, a preparation of human gonadotrophines (ovary stimulating hormones). Recently, Doctor Pietro Donini of Rome, Italy, found a way to extract the hormones from the urine of postmenopausal women. Retired nuns in Italy are the donors. Ten liters of urine are purified to produce one small pellet. The pellet, Pergonal, in sterile solution is injected to replace the lack of hormones and can make a woman potentially fertile whose cycling mechanism is out of order.

"Women patients are given a test to determine the amount of stimulating hormones in their urine, a test similar to the pregnancy test," Dr. Lamb explains, "then a simulated cycle is begun. The drug is injected for 10 days to prepare the ovary to release the egg. Then chorionic gonadotrophin, another stimulating hormone, is injected to release the egg. If fertilized, pregnancies can occur immediately."

Dr. Lamb estimates up to 20 percent of infertility in women is due to disorders of ovulation which can be corrected with these drugs.

Further research is being conducted by the staff of the Infertility and Gynecologic Endocrinology Clinic on the effects of the use of Pergonal and other stimulating drugs and their application to other areas of gynecology.

One use would be to perfect the rhythm system of birth control, Dr. Lamb said. If ovulation were induced on a schedule, a woman would know the exact days when she is able to conceive. At the present time, the limits of the fertile days are difficult to define, especially in women with irregular cycles.

The Palo Alto Hospital, now being renovated as part of the Palo Alto-Stanford Hospital Center, will be a leader in Western states, with life-saving monitoring equipment for cardiac patients, it was disclosed Wednesday at the meeting of the Hospital Board of Directors.

Gordon P. Smith, president of the Hospital Board, reported that a donation of $16,982 from the Palo Alto-Stanford Hospital Auxiliary will make it possible to buy and install the monitoring equipment and 10 electrically-operated beds, two of which are specially designed for cardiac patients. The contribution came from profits realized from the Hospital Gift Shop operated by the Auxiliary.

The sophisticated equipment will be installed in the 10-bed intensive care unit of the renovated hospital. Initially it will be used on four patients, and eventually it will be extended to eight.

Monitoring units on each bed will provide constant electronic surveillance of the acute cardiac patients and will relate information on the patient's pulse, heart rate and other aspects of his condition to a central alarm system in the nurses' station. With this information from the bedside monitors nurses and doctors will be able to respond immediately in cardiac emergencies.

Dr. Stanford Kroopf, a member of the Palo Alto medical staff and chairman of the committee which recommended the new program, said:

"Arteriosclerosis, which causes narrowing of the blood vessels and clot formation and leads to coronary occlusion and heart attacks is one of the chief causes of mortality in the country today. With better equipment, a large number of patients who die from heart disease could be saved. Men under 55 are affected with this type of heart trouble more frequently than women of this age bracket."

- more -

Dr. Kroopf cited a study showing that in one private hospital in Kansas City where similar equipment is used the mortality rate of acute cardiac patients was 19 per cent compared to 43 per cent for patients treated on the general hospital floors.

He added that according to the Public Health Service, 45,000 deaths occurring from heart disease could be prevented annually in the United States.

The monitoring units work simply. Each patient is connected to the machine by wearing a photocell earpiece. On the far side of the earpiece is an infrared light permitting rays to pass through the ear to the photocell. Each time the heart beats, it concentrates more blood in the ear, reducing the amount of light reaching the photocell. When the heart relaxes, the blood concentration diminishes, increasing light transmission through the ear.

One portion of the electronic monitoring unit is a small computer that counts the pulses of blood movement within the ear, providing a continuous indication of the patient's heart rate. Each machine can be pre-set for the desired low and high heart rate limits by the physician.

If the patient's heart rate exceeds these limits the nursing staff is notified by a red light or audio alarm. The equipment was developed by the Palo Alto firm of Corbin-Farnsworth, Inc.

The intensive care unit in the Palo Alto Hospital will be serviced by registered nurses who will be given an extensive indoctrination course in both care of the cardiac patient and in the use and operation of electronic equipment, Dr. Kroopf said.

The Palo Alto Hospital will provide 160 additional beds to the Hospital Center when it is completely renovated in Spring. The Hospital is designed as an acute unit for medical patients, with the standard of service and quality of care being available in the Palo Alto-Stanford Hospital.

FOR RELEASE THURSDAY, OCTOBER 29, 1964

A new, large-scale study of the pharmacology of anesthetics and related drugs will be launched at Stanford Medical Center, with a grant from the U. S. Public Health Service, it was announced today.

The research will be directed by the Department of Anesthesia of Stanford University School of Medicine. The grant, announced by Dr. Luther L. Terry, surgeon general of the Public Health Service, will provide $191,505 for the first year's activities of a proposed seven-year program. Funds will be administered by the National Institute of General Medical Sciences of the National Institutes of Health.

The research program will be the first of its kind on the West Coast supported by the Public Health Service. Two other multi-faceted research programs in anesthesia are at Columbia University in New York, and the University of Pennsylvania in Philadelphia.

Dr. John P. Bunker, professor of anesthesia, will be the project director, and Dr. J. Weldon Bellville, associate professor of anesthesia, will be associate project director. They will coordinate the activities of a team of senior scientists aimed at developing more precise methods of measuring effects of anesthetics and related drugs than currently available.

Dr. Bunker emphasized the current need for extensive and detailed knowledge of the pharmacology of anesthetics and the clinical problems they present so that physicians can cope with undesirable side effects, many of which are poorly understood at present.

- more -

Physicians can use the drugs safely, Dr. Bunker said, but they need to know more about how the drugs act, especially if more than one drug is used simultaneously. Where do they go in the body? How do the different organs react to them? Are they metabolized (burned up) or excreted and how?

For example, in one national study coordinated by Stanford, investigators have been trying to determine whether the gas halothane, used for thousands of operations yearly, causes liver damage. It has been suggested that an impurity in manufacture, present in minute quantities, may be responsible for the rare instances of liver damage which have occurred.

But, Dr. Bunker commented, the scientists find themselves looking for a complication that may occur once in 10,000 cases, and trying to evaluate the possible harm of a substance which occurs as a contaminant one part in 10,000.

These are "needle in a haystack" problems of great difficulty, Dr. Bunker noted, but they become increasingly important to the field of postsurgical care as advances in clinical applications are made and as surgical techniques become more complex.

Therefore, the study at Stanford will focus on dose-effect relationships, side effects, toxicological effects, drug interactions, and the uptake and distribution of drugs.

Precise information concerning the uptake and distribution of drugs is necessary, Dr. Bunker explained. He cited the research of Dr. Ellis Cohen, associate professor of anesthesia at Stanford, who recently extended the work of other researchers on the problem of distribution of curare.

Curare is the poison South American natives put on the tips of their blowpipe darts. Although it has been known since the time of Columbus, it was not

used as aid to anesthesia until the early 1940's. The introduction of curare as a muscle relaxant probably represents the single greatest advance in anesthesia in recent years. But physicians until recently were not sure where the curare goes and how long it stays in critical parts of the body. Dr. Cohen's work has confirmed the importance of the kidney in the elimination of this compound and has provided new information concerning the role of other organs.

The proposed study in anesthesia will be conducted in collaboration with other departments of the School of Medicine, and the University. These include the departments of preventive medicine (bio-statistics), the computation center, the departments of chemistry and statistics of the School of Humanities and Science, and the School of Engineering.

The field of anesthesiology has been identified by the National Institute of General Medical Sciences as a research area of special need, and Congress three years ago directed that additional funds be allocated for the support of anesthesiology research and research training.

Prior to assuming his present position in 1960, Dr. Bunker was assistant clinical professor of anesthesia from 1952 to 1960 at Harvard University Medical School. During this time he was also an associate anesthesiologist at Massachusetts General Hospital in Boston.

A native of Boston, Dr. Bunker received his undergraduate degree in 1942 and an M.D. degree in 1945 from Harvard University. He is the author of numerous scientific articles dealing with metabolic effects of anesthesia.

A new book dealing with hearing and hearing disorders has been published by Dr. Hayes A. Newby, director of the Division of Speech Pathology and Audiology at Stanford University School of Medicine.

Although it was not written directly for laymen, readers will find that "Audiology" has information of value, presented in an understandable manner.

Audiology, Dr. Newby explains, refers to the study of hearing and hearing disorders and the book is for those primarily interested as professionals in this broad field. But the hard of hearing and those close to them will find their problems, both physical and psychological, discussed in layman's style, especially the chapters on rehabilitating the hard of hearing adult and training the hearing impaired child.

The book also contains valuable information on lip reading, hearing aids, and other equipment, and points out the need of seeking professional advice upon the first indication of hearing impairment.

Dr. Newby wrote the first edition of "Audiology" in 1958. The new completely revised edition attempts to integrate the latest information on developments that have occurred in this field in the past six years. The book was published by Appleton-Century-Crofts of New York.

Dr. Newby has been on the Stanford faculty since 1947. In addition to his teaching duties at Stanford he was director of the San Francisco Hearing and Speech Center from 1948 to 1956 and is currently consultant to that organization as well as the Veterans Administration.

Dr. Newby is presently president of the American Speech and Hearing Association, which will be holding its 40th annual convention in San Francisco November 21-24.

For the past eight years, Dr. Newby has been associated with the weekly television program "Doctors News Conference," and has been program moderator for the past three years.

FOR RELEASE SATURDAY, OCTOBER 24, 1964

Complete cure of "blue baby" heart defects can now be accomplished with negligible risk, a team of surgeons from Stanford University School of Medicine reported today.

Dr. Norman E. Shumway, associate professor of surgery, told the scientific sessions of the American Heart Association in Atlantic City that no deaths occurred in 43 consecutive operations performed in the Palo Alto-Stanford Hospital during the last four years on "blue baby" patients ranging in age from 17 months to 45 years.

He explained that although the procedures for complete surgical cure were developed nearly a decade ago, there has been considerable reluctance on the part of many surgeons to use them because mortality rates of 15 to 20 per cent were prevalent until recently. Instead they relied on older techniques which relieve but do not cure the condition.

The "blue baby" patients described by Dr. Shumway's report were born with a combination of defects called tetralogy of Fallot (for the 19th century French physician who first described the disease). The two main defects of the four characterizing the condition are: (1) an opening between the normally separate lower chambers of the heart, the ventricles and (2) a narrowing of the pulmonary artery through which "used" blood returning from the body is carried to the lungs for oxygen replenishment.

- more -

As a result of these defects, de-oxygenated ("blue") blood makes its way into the left side of the heart through the hole between the ventricles and is pumped to the body, imparting a bluish tinge to the patient's skin.

For complete repair of blue-baby defects, surgery must be performed on the heart itself. This requires the use of a heart-lung machine which assumes the job of pumping blood to the rest of the body, enabling the surgeon to operate on a relatively dry and bloodless heart.

The practice at Palo Alto-Stanford Hospital, Dr. Shumway noted, is to undertake total correction in each patient who suffers from "blue baby" heart defects and weighs more than 22 pounds. Severely ill, smaller patients undergo surgery that relieves the condition until curative surgery can be performed later. Sixteen of the 43 patients in the Stanford series had previously had such a palliative operation.

The heart is cooled, Dr. Shumway said, until it stops beating. Repair is made by cutting a small hole into the right ventricle and sewing a plastic patch over the hole between the lower pumping chambers. The "tightness" of the pulmonary artery is relieved either by cutting away muscular tissue narrowing the vessel's outflow tract or by enlarging the tract with a plastic patch. Surgery takes from 40 minutes to one hour.

Follow-up studies by Dr. Shumway and his associates, Drs. Richard R. Lower, Edward J. Hurley and R. Cree Pillsbury--show that almost all the patients now have normally functioning hearts and can participate in normal physical activity.

Note to editors: This paper will be presented Tuesday, December 1, at the afternoon session of the Radiological Society of North America meeting in Chicago.

--

Men with localized cancer of the prostate can now be treated relatively simply by external radiation therapy, with the prospect of cure being at best as good as that following radical surgery, it was reported Tuesday to the Radiological Society of North America.

Furthermore, cure can be achieved without sacrificing the patient's virility which happens when the disease is contained by surgical removal of the prostate.

Dr. Malcolm A. Bagshaw, Dr. Henry S. Kaplan, and Dr. Robert H. Sagerman of the department of radiology at Stanford University School of Medicine said that prostate cancer treated radically by external radiation therapy produced "striking alleviation of local symptoms in all but nine of 73 patients."

After five years 13 of 30 patients treated at Stanford are still living without evidence of disease. Of the entire group of 73, 49 patients are living although some have not been followed for five years. The survival rate for the entire group was 54 per cent.

The physicians explained that success of the treatment partly depends on pinpointing accurately the position of the tumor and then de-

- more -

livering a high dose of radiation homogeneously to a small volume of tissue. This can be accomplished by special X-ray techniques.

The radiation dose used on patients was 7000 rads over a period of six weeks. It was provided by a high energy X-ray beam from the Stanford medical linear accelerator.

"We believe," the Stanford physicians said, "that this study has demonstrated a new approach to the treatment of localized carcinoma of the prostate, an approach which promises survival rates comparable to those achieved by radical surgery with less hazard to the patient and less disturbance of normal function."

Indeed, they added, some patients whose cancer is too advanced for surgery may now be treated.

For the most part, aggressive radiation therapy of the prostate does not seem to alter the patient's sexual potency, the physicians reported.

Reliable data on sexual activity was obtained on 18 patients, 14 of whom claimed to have noted no change in their sexual habits. Four patients noted a definite decrease.

A significant finding was that patients whose prostate cancer was less than a year old when treatment began have had a higher survival rate than those who had the disease longer.

This would indicate that the discovery of prostate cancer early gives the patient an excellent chance for cure. Since in most cases the cancer can be detected by a simple examination by the patient's family doctor, no man can fail to concede the value of regular medical checkups, the physicians said.

Cancer of the prostate is responsible for some 10 per cent of cancer deaths in men.

The disease may produce two quite different kinds of symptoms. One kind, due to the enlargement of the prostate itself, consists of urinary difficulty. The other is pain in other parts of the body, for instance in the lower spine, resulting from spread of the disease to the bones of the skeleton.

Subject: Evoked vocalization in the rhesus monkey.

Author: Bryan W. Robinson, M. D., Section of Neuropsychology, Laboratory of Psychology, National Institute of Mental Health, Bethesda, Md. (Present address: Division of Neurology, Stanford Medical School, Palo Alto, Calif.)

Address: Division of Neurology, Palo Alto-Stanford Hospital, Palo Alto, Calif.

Time: December 30, 1964 p.m.

Place: Queen Elizabeth Hotel

Program: Symposium on Communication and Social Interaction in Primates

Convention Address: Queen Elizabeth Hotel

Based on more than 5,000 electrical stimulations of the brain of the M. mulatta monkey, the author was able to locate fairly completely those areas and structures which are responsible for vocalization. At least three different types of vocalization were identified, and these appeared to be correlated with sexual, aggressive, and alimentary changes. When these responses were carefully mapped, it was found that several neural systems could be identified. These neural systems were primarily in the limbic system and related structures. Analysis of the details of localization has contributed to a better understanding of the general rules of structural and functional organization in this part of the brain, and supports the hypothesis that a wide variety of functional systems are tightly interwoven into a fabric-like arrangement. Mathematical analysis of the arrangement of the individual 'threads' of the system suggests that this arrangement approaches randomness. The significance of this finding is that it provides a model and a mechanism which can account for the flexibility and variety of the association of behaviors seen in both normal and abnormal primate and human behavior.

STANFORD MEDICAL CENTER NEWS BUREAU
Palo Alto, California

FOR FURTHER INFORMATION CONTACT: Helen Connolly (321-5310)

New visiting hours will go into effect Friday at the Palo Alto-Stanford Hospital. They will replace the present policy of open visiting hours.

Maternity patients may be visited from 3 to 4:30 p.m. and 7 to 8:30 p.m. every day. Newborn babies will be shown during the same period. Other patients may be visited from 2 to 4 p.m. and from 7 to 8:30 p.m.

Exceptions are patients in the intensive care unit, patients on the day of surgery and children, who may be visited by members of the immediate family any time with permission from the physician or head nurse.

Dr. LeRoy E. Bates, director of the Hospital, said that limitations on visiting hours were necessary for the care and comfort of patients.

"Visitors provide a welcome diversion to patients," he explained. "However, we must ask our visitors to keep their visits short, no more than 20 minutes in general or 10 minutes in the intensive care unit. Most people when they are sick can enjoy company for only a very short while."

No more than two visitors for each patient can be permitted in the room at one time, Dr. Bates stated. Other rules, still in effect, are that children under 16 may not visit the pediatrics or maternity sections, and children under 10 are not allowed in the general sections of the Hospital unless they are visiting an immediate member of the family.

Almost three years after being crippled by a major stroke, Palo Alto attorney Donald E. Glass, 35, returned to full time law practice today, with a triumphant smile on his face.

As he walked into his newly decorated office, Glass was resuming a trip that started on a crisp morning just before Christmas in 1961.

He was on the way to work that morning when his right hand "buzzed" momentarily with a "pins and needles" feeling. Maybe, he thought, my arm is asleep.

But minutes later after he had entered the office, Glass began to feel faint, lost his balance and collapsed.

Immediately, he was taken to the Palo Alto-Stanford Hospital Center where surgeons worked diligently to save his life by removing a damaged blood vessel from his brain.

When the operation was over his road to recovery had hardly begun. The stroke had left his entire right side paralyzed. He was unable to stand, walk, speak or remember. Doctors generally agreed that his chances to work again were slim.

But his family physician, Dr. Russell V. Lee of the Palo Alto Medical Clinic did not agree. "There is no doubt in my mind that someday you will be able to practice law again," Dr. Lee had told him.

It took actually three years and the efforts of a Stanford team of rehabilitation specialists to restore Glass to useful independence.

- more -

A stroke is a form of a breakdown in the supply of blood to the brain. When the flow to any section of the brain is interrupted, it dies along with its function--control of a limb, an area of memory, speech, vision or any of hundred abilities.

Persons afflicted by major strokes rarely do useful work again, said Dr. Daniel J. Feldman, director of the Division of Rehabilitation Medicine at Stanford Medical School. But their loss has become needless. We know now enough about strokes to be able to reduce the present atrocious waste of lives.

"Glass is an example of a brilliant lawyer who made a spectacular comeback with restorative care," Dr. Feldman said.

Today, Glass can stand and walk. He can bowl and go skiing--two of his favorite sports. Slowly, his muscles have been rescued from atrophy. Alternate nervous pathways have been trained with physical and occupational therapy. For almost a year he was totally unable to speak. Now he can speak and dictates seven to ten letters a day.

Glass still has a considerable limitation of movement in his right extremities. But his chances for improvement are good because of a new technique now being studied at Stanford.

The new technique involves the treatment of taut muscles through injection of drugs into nerves and nerve roots. This method is being evaluated and refined by Dr. Jordan Katz, assistant professor of anesthesia, in cooperation with Dr. Feldman, Dr. Leslie Knott, assistant professor of medicine, and others in the Division of Rehabilitation Medicine.

Six months ago, Dr. Katz injected a muscle-relaxing drug in Glass' right arm that has relieved the rigidity of elbow and shoulders. Although it is far from a cure-all, the technique holds promise when used in conjunction with physical and occupational therapy.

Glass attributed his recovery not only to the fact that rehabilitation began soon enough after the stroke, but also because "I suddenly realized that after a frightful incident such as this a person can draw upon hidden resources. As soon as I had regained consciousness from the operation I felt I should just get out of bed and walk."

He tried it, in fact, in the hospital when the nurses were not looking.

Speaking came harder to Glass. In his words, "It was like trying to penetrate a concrete wall." His first hint that he would speak again was when a group of students came to the Hospital to sing Christmas carols in 1961.

"I suddenly realized that I could sing," he said. But his speech did not return until later.

Glass, his wife Laddie and children, Mike, 10, Cindy, 7, and Steve, 6, live at 3314 Cowper. He is a Stanford University graduate and was editor of the Stanford Law Review in 1952.

He is currently serving on the California State Department of Social Welfare's advisory committee for aiding needy disabled persons.

GLASS STORY - ADD AFTER FOURTH GRAPH ON PAGE TWO

In the beginning Glass had difficulty with what he termed his "current memory." He could not recall something that had happened five minutes earlier.

He discussed the problem with his doctors who told him that he could train his memory by going way back to his childhood and recalling his entire life.

Consequently, on leaving a rehabilitation clinic in New York to return to the West Coast, Glass took a cross-country bus instead of a plane.

He went to Washington, D.C. to visit a hotel where he had often stayed; to Des Moines, Iowa, where he was born; to Denver, Colo., where he had attended elementary school; to Salt Lake City, where he had visited; and to Pomona, where he had spent his high school days.

"This process really helped my memory considerably," he said.

PICK UP "Glass still has a considerable etc.

Dr. Tinsley R. Harrison, a noted authority on cardiovascular diseases, will give the first John Kent Lewis Memorial Lecture, sponsored by the Stanford University School of Medicine.

He will speak on "Some Problems in the Diagnosis, Management, and Pathophysiology of Angina Pectoris". The lecture will be given Wednesday, December 9 at 7:30 p.m. in Room M106.

Dr. Harrison is professor of medicine of the Medical College of the University of Alabama. He is a distinguished teacher and writer. He wrote Failure of the Circulation, and is chief editor of the prominent textbook Principles of Internal Medicine. He received his A.B. from the University of Michigan and his M.D. degree from Johns Hopkins University School of Medicine. He received his residency training in internal medicine both at Peter Bent Brigham Hospital in Boston, and Johns Hopkins Hospital in Baltimore.

In 1941, Dr. Harrison became professor of medicine at Bowman Gray School of Medicine, and also served as physician-in-chief of North Carolina Baptist Hospital at Winston-Salem, N.C. From 1944 to 1950 he served consecutively as dean of the faculty and chairman of the Department of Medicine of Southwestern Medical School, and was also physician-in-chief of the Parkland Hospital in Dallas. In 1950, he joined the faculty of the University of Alabama.

He is a diplomate of the American Board of Internal Medicine and past president of the American Society for Clinical Investigation and the American Heart Association.

The lectures are dedicated to the memory of Dr. John Kent Lewis who died in 1961. Dr. Lewis was professor of medicine and chief of the Stanford Medical Service at San Francisco General Hospital. With his Stanford professors, A. W. Hewlett and George D. Barnett, Dr. Lewis had published some of the early work on vascular sounds, exercise and respiration. He was one of the first to study thyroid hormone in relation to the heart. He was also well known for his pioneering studies on heart sounds and cardiac arrhythmias.

Dr. Lewis had served as president of the San Francisco Heart Committee and the California Heart Association.

A new study into the causes and cure of amyotrophic lateral sclerosis will be launched at Stanford Medical Center, it was announced today.

Amyotrophic lateral sclerosis is an invariably fatal disease of unknown cause in which motor nerve cells, those which control muscular contraction, are gradually destroyed.

Dr. Sidney Raffel, acting dean of Stanford University School of Medicine, said that the new study will be made possible by a $50,000 fund established by Raymond J. Schirm of Brea, Calif. The fund was established in memory of Mr. Schirm's wife who died of the disease earlier this year. It will be known as the Mildred Ellingwood Schirm Memorial Fund for the study of Neurological Diseases.

"It is my hope," Mr. Schirm said, "that by providing some assistance to those who seek more knowledge of neurological conditions, medical science may learn what causes amyotrophic lateral sclerosis, and may develop methods of detection which will lead to prevention and control of the disease."

Principal investigator will be Dr. Frank Morrell, chief of the Division of Neurology at the School of Medicine.

Dr. Morrell explained that it has been particularly difficult to study the disease because of the lack of refined and precise techniques, and also because there are no animals known to have it. The study of the disease has further been frustrated by the problem of getting diseased tissue in form suitable for observation.

- more -

Recent developments, however, may have opened the way for profitable work.

"It is now possible," Dr. Morrell said, "to do precise chemical analyses of extremely small tissue samples--even as small as a single cell. The various kinds of nerve cells have different functions and different structures as seen under the microscope. These differences, in turn, must reflect individual variation in biochemical composition.

"Amyotrophic lateral sclerosis is a disease which selectively affects nerve cells connected with the motor system while leaving nearby sensory cells intact. Therefore, if one could identify the exact nature of the biochemical difference between, for example, motor and sensory cells, the information should provide a clue as to the cause of the disease and perhaps lead to prevention or treatment."

Recent developments in electronics and computer sciences have made it possible to distinguish motor from sensory cells with sensitive electrical tests, Dr. Morrell said. The next step is to apply the biochemical techniques mentioned earlier to each type of nerve cell separately.

Mr. Schirm whose gift will make this work possible is a member of an old established family in Southern California. The J. S. Schirm Company of San Diego was founded in 1885. The Company specializes in the distribution of construction materials and manufacture of portland cement. Mr. Schirm has two sons, David and Jack, who are active in the business and a daughter, Mrs. Harry R. Carlton of Laguna Beach.

A Nobel Prize winner in the study of virus diseases, Dr. Frederick C. Robbins, will give the first annual Harold K. Faber Lecture in a symposium on Chronic Diseases of Childhood February 6.

The one-day symposium, which begins at 8:30 a.m., is sponsored by the Stanford Children's Convalescent Hospital and the department of pediatrics of Stanford University School of Medicine. It honors Dr. Harold K. Faber of San Francisco, emeritus professor of pediatrics and former executive head of the department before his retirement in 1949. He also was medical director of the Convalescent Hospital for 39 years.

Dr. Faber is internationally known for his polio research and for his teaching and clinical work.

Dr. Faber will introduce Dr. Robbins who is professor and chairman of the department of pediatrics at Western Reserve University. Dr. Robbins will speak on "A Biographical Sketch of Poliomyelitis" at 2:30 p.m.

His lecture is one of five presentations that day in Physics Hall, Room 100. Other speakers will be Dr. Alfred M. Bongiovanni, professor and chairman of the department of pediatrics at Children's Hospital of Pennsylvania; Dr. Urie Bronfenbrenner, professor of child development and human relations at Cornell University; Dr. Leon Eisenberg, professor of psychiatry and director of Children's Psychiatric Service at Harriet Lane Home of Johns Hopkins Hospital; and Dr. Irving Schulman, professor and chairman of the department of pediatrics at University of Illinois Research and Education Hospitals.

- more -

Dr. Robbins received his A.B. in 1936 from the University of Missouri and his M.D. from the Harvard University School of Medicine. He completed his residency training in bacteriology and medicine at the Children's Hospital in Boston, and in 1948 he became research fellow in pediatrics at the Harvard Medical School.

Dr. Robbins was appointed by the National Research Council in 1948 as a senior fellow in virus diseases to work with Dr. John F. Enders in the research division of infectious diseases at the Children's Hospital in Boston. The two men investigated properties of the mumps virus and the growth of poliomyelitis viruses in tissue culture.

He joined the Western Reserve University School of Medicine as professor of pediatrics in 1952.

He continued his research, and in 1952, he, Dr. Enders and Dr. Weller received the Nobel Prize in physiology and medicine.

Other honors include Doctor of Science degrees from John Carroll University and the University of Missouri. He is past president of the Society for Pediatrics Research.

A tilt table to test the balance of dizzy patients is the newest addition to a unique testing laboratory of the Ear, Nose and Throat (ENT) clinic of the Stanford University Clinics.

Dr. Richard Goode, resident in ENT, and Dr. F. Blair Simmons, assistant professor of surgery, have devised the tilt table with $9 worth of parts from a surplus market. The table is used in connection with a new electronic machine costing $3,500 called an electronystagmograph, found only in major medical centers around the country.

Stanford's balance testing laboratory now offers a combination of equipment -- old and new, costly and inexpensive --some "home-made" and some of the latest electronic gadgets, all designed to provide the most complete and accurate examination possible to locate the cause of dizziness.

Most types of dizziness are due to disorders of the inner ear, Dr. Goode explained. Other causes are head and neck injuries from falls, whiplash in auto accidents, nervous and systemic diseases, and drugs. The recent experiences of several astronauts with balance problems has pointed up interest in this field.

The dizzy patient will usually be given a general physical checkup by his physician, who will look for signs of high blood pressure, anemia or heart disease. When no definite cause is found, many patients are referred to Stanford's ENT clinic where a complete ENT exam is done as well as audiologic tests for hearing. Usually neurologic examinations are also made.

Following this, the still dizzy patient comes to the balance testing laboratory. Here the patient is placed on the tilt table and sensitive electrodes are attached beside his eyes to pick up eye movements as his position is changed. Abnormal eye movements, which indicate disorders of the balance system, are recorded on graph paper.

-MORE-

A century old test, in which water of varying temperature is put in the patient's ears, is still used. But now the electronystagmograph records the response instead of the doctor relying on his naked eye.

A platform has also been built by Dr. Goode, on which the patient stands so that the least change in his balance, caused by galvanic stimulation of the mastoid, can be recorded.

With the exact knowledge which can be gained from this battery of diagnostic instruments, it is now possible to pinpoint the location and cause of a person's dizziness, Dr. Goode pointed out. Serious neurologic disorders can be differentiated from less serious inner ear problems. Certain types of dizziness can be cured with new surgical procedures. It is also possible to find cases in which special training of balance is the solution.

Dr. Goode's research on new ways of testing balance and evaluating dizziness is financed by the National Institutes of Health.

A new machine is being used in the Palo Alto-Stanford Hospital Center to map the brains of patients for signs of injuries, tumors or other diseases.

Called an echoencephalograph, the instrument works on the same principle as radar. It sends ultrasound waves from a crystal which then listens for echoes. The echoes are traced on an oscilloscope screen and the tracings are photographed by a polaroid camera.

According to Dr. Douglass F. Adams, resident in radiology, the echoencephalograph is a safe, new diagnostic instrument which detects problems that X-rays may not be able to find. It is also easier to use and less expensive than an X-ray machine. The echoencephalograph is compact enough to be wheeled around on a cart and brought to a patient's bedside. It can be used for abdominal, heart and eye examinations and to measure the fetus of a pregnant woman. It is absolutely safe for repeated use, he said.

Also called an "ultrasonogram," the new machine will not supplant the X-ray, but will supplement it, Dr. Adams pointed out. The echoencephalograph is particularly useful in showing changes in soft tissues that X-rays can't detect. In examining neurology patients, the echoencephalograph locates the midline of the brain. Any shift in position of the midline indicates trouble.

The echoencephalograph is operated by a physician. He holds a small metal cylinder, the crystal transducer, against the patient's skin while the sound waves probe inside. The machine makes no noise, requires no special environment. An examination takes but minutes. Further uses of ultrasound diagnosis are being explored at the Hospital.

Have you ever wondered what it would be like if no one understood what you said?--if you heard various speech sounds but could not repeat them properly? You would simply have to rely on gestures and facial expressions to communicate.

This was the case with four-year old Howie. When his mother brought him to the Stanford Speech and Hearing Clinic last October, she described him as having "his own language." After four months his speech improved. Various clinical exercises taught him to associate sounds with objects. As his vocabulary increased, he put words together in sentences.

Howie is one of the 150 patients who come to the clinic each year with disorders of speech, hearing or both. He is one of eight million Americans whose communication is diminished because of hearing or speech difficulties. Serving both children and adults, the clinic is operated by the division of speech pathology and audiology of the Stanford University School of Medicine.

Last year, the clinic held approximately 6,000 therapy sessions of 30 to 40 minutes in length, made about 250 diagnostic evaluations for speech and about 750 evaluations for hearing.

The staff of the clinic includes Dr. Hayes A. Newby and Dr. Virgil A. Anderson, directors; Dr. Richard F. Dixon, supervisor of clinical audiology; Dr. John F. Font, supervisor of the training clinic; Mr. Gordon Duck, supervisor of the service clinic; and Miss Virginia L. Puich and Mrs. Ellen H. Seefeldt, assistant clinic supervisors. About 60 students work with patients.

Dr. Newby pointed out, "Many of these students are working for clinical certification from the American Speech and Hearing Association, as well as for M.A. or Ph.D. degrees, so their work is closely supervised by the staff."

-MORE-

Before Howie was admitted to the clinic, the staff gave him a complete speech and hearing evaluation. This is done for all cases, because a disorder may stem from one or more complex causes such as brain injury, prolonged illness, inadequate hearing, defective speech mechanism or mental deficiency. Howie's speech problem was not organic. His speech was unintelligible because he had simply failed to learn how to form speech sounds correctly.

When therapy began, Howie found it difficult to sit still. An active child, he had to be taught to listen, sit, and pay attention. Attending nursery school helped him learn to follow directions and to speak with children his own age.

In therapy sessions Howie likes to talk on a toy telephone, a valuable aid in speech training. The clinician hoped that Howie would connect his mouth movement with the common words said over the telephone. Now Howie can carry out spontaneous telephone conversations with him.

Another tool clinicians use to teach patients to speak correctly is a toy mailbox. They may ask a child to "mail a letter in the mailbox." Children soon learn how to form the "m" of "mail" with their lips.

"We have found that many problems in speech stem from problems in hearing," said Dr. Font. "This is why patients receive a hearing test as part of the evaluation before a decision is made regarding admission to the clinic."

The clinic doctors further believe that "deaf" children have some residual hearing but they have to be trained to use it effectively. Some children don't even know that sound exists unless they are taught about it. What the clinician does is to train the severely hard-of-hearing child to utilize all his residual hearing, as well as to take advantage of visual clues in speech (lipreading).

Testing consists in part of determining the threshold, the point where a patient first hears a sound. The patient raises his hand when he first hears the sound coming from an audiometer, an instrument which emits tones at varying levels of loudness.

This was the case for Maria, a three-year old child who could not hear any sounds well. In the clinic, she uses an auditory training unit which is adjusted so she hears sounds of a much greater range than can be detected with the hearing aid she normally wears at home.

It's a tough job to get a young child like Maria to use her own voice. But first you have to make her aware that she has a voice. Clinicians train patients with hearing problems to recognize, then to say words.

"What we're really aiming at," Dr. Anderson says, "is a sort of matching game. The children match what they see--a toy, for instance--with the corresponding movement of the mouth of the clinician who is saying the name of the toy."

Throughout therapy, parents are encouraged to observe through a one-way window in an adjoining room. This is part of the program to enable family members to understand the techniques employed in the clinic so they can carry them out at home.

The Stanford Medical Center is one of the few centers in the country offering a full range of patient services in speech and hearing in conjunction with a teaching program in speech pathology and audiology.

Note to Editors: This story was transmitted on Business Wire February 18, 1965.

Dr. Robert J. Glaser, 46, president of Affiliated Hospitals Center and professor of social medicine at Harvard Medical School, today was appointed dean of Stanford University School of Medicine and vice president for medical affairs. He also will serve as professor of medicine.

His appointment, culminating an eight-month nationwide search for a dean by a special faculty committee, was announced by President J. E. Wallace Sterling.

Dr. Glaser will succeed Dr. Sidney Raffel who has been acting dean since Dr. Robert Alway resigned a year ago to return to full time teaching. Dr. Raffel will resume his duties as professor and executive head of the Department of Medical Microbiology. Dr. Glaser's appointment will become effective in July.

"Dr. Glaser brings to Stanford an unusual combination of academic and administrative experience," President Sterling said. "He is nationally recognized for his concern to bring to patient care the best that medical science and teaching can provide.

"He has had experience in building a medical center, having completed one at the University of Colorado where he served as vice president for medical affairs and dean. For the past two years he has been associated with an ambitious and unique project which envisions a new kind of hospital complex in the vicinity of Harvard Medical School. The Stanford University School of Medicine is fortunate to be able to draw on Dr. Glaser's talents as scientist, teacher, and administrator."

A graduate of Harvard College in 1940 and the Harvard Medical School in 1943, Dr. Glaser interned at the Barnes Hospital in St. Louis, Mo. After completing his residency training in medicine at the Peter Bent Brigham Hospital in Boston and the Barnes Hospital he joined the faculty of Washington University School of Medicine in 1947.

-MORE-

His academic and administrative positions included assistant professor of medicine, associate dean of the faculty of medicine, and associate professor of medicine. He also acted as chief of the Division of Immunology from 1954 to 1957. In 1957 he became dean and professor of medicine at the University of Colorado School of Medicine.

Dr. Glaser returned to Harvard in 1963 to coordinate the planning of a new hospital complex which would tie in Harvard Medical School with six affiliated hospitals. Throughout his professional life, Dr. Glaser has devoted a large portion of his research activity to the rheumatic diseases. He was chief of the Rheumatic Fever Clinic in the Washington University Clinics, consultant in rheumatic fever to the State of Missouri Crippled Children's Service, and consultant in rheumatic disease to the University of Illinois. Dr. Glaser also has served as a member of the scientific advisory council of Rheumatic Fever Institute and the committee on prevention of rheumatic fever and bacterial endocarditis of the American Heart Association. He is presently a member of the National Health Research Facilities Advisory Council of the U. S. Public Health Service.

His publications include more than 40 papers, most of them dealing with experimental streptococcal infections and rheumatic fever.

Dr. Glaser also holds memberships in the medical honorary society Alpha Omega Alpha, the society of Sigma Xi, the American Society for Clinical Investigation, and the Association of American Physicians. He is currently the editor of Pharos, the national publication of Alpha Omega Alpha.

Dr. Glaser was born in St. Louis, Mo. He is married and has three children. Mrs. Glaser is also a physician, having received the M.D. degree in 1947 from the Washington University School of Medicine. Her specialty is pediatrics.

First prize winner in the Stanford Medical Center Art Show's painting category for the second year was Leonard Winograd, senior laboratory technician in the department of dermatology of Stanford Medical School. His painting, "Coit Tower", was in oil.

Mary Kay Walker, research technician in the division of infectious diseases of the Stanford Medical School, was runner-up for her work entitled "Night Birds", a painting in various blue tones.

Dr. Raymond C. Stofer's "Yeah Yeah Yeah" sculpture made from iron boiler plate also won a first prize. He is research associate in surgery at the Medical School.

In photography, Glenn Battle, clinical laboratory technician, won first ribbon for pictures of three towheaded children entitled "Once upon a time".

Other first place winners were: Dr. Stanford S. Kroopf of the Palo Alto medical staff for his mosaic, "Owl"; Molly Babington, Auxiliary, for her collage, "Fairy Flowers"; and Peter Engel, fifth year medical student for his print entitled "Tree".

Other runner-ups were: Molly Beth Jones, candy striper, for her cat sculpture; Dr. Allen Gates, assistant professor in obstetrics and gynecology for a photograph, "Dew Coats a Cobweb"; David B. Starkweather, associate administrator of the Hospital, for a mosaic, "Avocets"; Dr. Carl Brunsting of the Palo Alto medical staff for a sail boat mobile; and Molly Babington, Auxiliary, for an ink sketch entitled "The Banyon Tree".

More than 80 entries were submitted in the Feb. 8 through 12 Art Show. Winners were chosen by a popular vote of over 300 viewers.

A new grant of $25,000 has been made by the California Elks to the Palo Alto-Stanford Hospital Center for the care of needy handicapped children.

A similar grant, made a year ago, provided aid for almost 100 children from 20 counties in California, according to Gerald C. St. Denis, chief clinical social worker at the Center.

The grant will again pay for laboratory tests, treatment, surgery, medicine, transportation and housing expenses for parents, if needed, when they are from out of town and must stay nearby while the child is temporarily hospitalized.

In presenting the check, John Morey of Menlo Park, treasurer of the Elks, said, "With the renewal of this grant for 1965, the Elks, along with the doctors and staff at the Palo Alto-Stanford Hospital Center, look forward to another year of great accomplishments in meeting the needs and enriching the lives of handicapped youngsters."

Children being helped by the grant include those suffering from defective hearts, blood disorders, asthma, kidney disease, eye conditions, speech problems and orthopedic handicaps. Others, who fail to grow normally, or who have emotional problems associated with handicaps, are also aided. Through the Elks support, the complete needs of each individual can be considered, Morey pointed out.

The children who receive help are recommended by referring physicians and screened by social workers at the Center. The program is under the direction of the department of pediatrics of the Stanford University School of Medicine.

Thoughtful builders working on the partially completed Clinical Sciences Research Building of Stanford University School of Medicine will tip-toe around the noise problem of getting through walls by using new concrete cutting techniques.

"The builders are using 'silent drilling' so patients in the adjacent Palo Alto-Stanford Hospital may rest in quiet," said Frank Vitale, assistant administrator.

The drilling is necessary for constructing the corridor openings from the new building to the East Hospital Pavilion, Boswell Building and Medical School. Workers are using an extremely hot torch to penetrate and cut the concrete. Then, a small core of concrete is lifted out of the building.

The noiseless process eliminates the need for chipping guns and jack hammering, two cheaper techniques which have caused loud vibrations in that area previously.

Workmen direct the torch nozzle at the concrete wall where its tip blazes at 12,000 degrees F. It cuts through concrete one inch per minute. Molten cement runs out of the gap like lava from a volcano, but workmen can touch the concrete less than a foot from the torch without feeling heat.

The torch throws a flame consisting of a mixture of oxygen and propane which has been preheated. At the tip aluminum oxide powder is injected and the flame hits the wall at a pressure of 105 pounds per square inch.

Core and Flame Cutters, Inc. of Los Angeles, California, are in charge of the operation.

The new building is scheduled for completion Dec. 31, 1965. At present, the building is 55% complete.

-More-

When completed, it will consist of four stories--a basement and three floors--covering 152,000 gross square feet, about twice the size of existing hospital pavilions.

The new structure will contain facilities for investigation in medicine, surgery, radiology, pediatrics, genetics, obstetrics, and psychiatry.

It will also include the Lt. Joseph P. Kennedy, Jr., Laboratories for Molecular Medicine where basic research will be undertaken related to causes of mental retardation.

Part of the new building will house facilities, supported by the National Aeronautics and Space Administration, for research in the fields of space biology and biomedical instrumentation.

The new Clinical Sciences Research Building is the first major addition to the Stanford Medical Center since it was constructed five years ago. It is financed in part by Stanford University's PACE Program (Plan of Action for a challenging Era) and by government grants for research facilities.

The largest PACE gifts were two of $1 million each from the Rockefeller and Joseph P. Kennedy, Jr., Foundations. Government grants include $2,033,918 from the National Institutes of Health, and $535,000 from the National Aeronautics and Space Administration.

The total cost of the building is $6,150,000.

FOR RELEASE IN P.M. NEWSPAPERS FRIDAY, FEBRUARY 12, 1965.

PHILADELPHIA--A new technique of detecting heart graft rejection has enabled Stanford University surgeons to keep a dog alive for eight and a half months with a heart transplanted from another dog, the surgical research team reported today.

Onset of rejection can be detected by a reduced electrical output of the heart muscle, measured by a widely used diagnostic tool, the electrocardiograph. Once rejection starts, drugs can be given to stop rejection. Then the drugs are stopped until rejection starts again.

The new technique allows the scientists to avoid continuous therapy with the drugs, which have dangerous side effects. The treatment program is similar to that used for patients with kidney transplants, but until now it has not been possible to spot the onset of rejection of grafted hearts.

The surgeons said that the dog has survived far longer than those treated in any other laboratory. They predicted that with their present knowledge they should be able to treat animals so that longer and longer survival will be possible.

The report was presented this morning at a meeting of the Society of University Surgeons by Dr. Richard Lower, assistant professor of surgery at the Stanford University School of Medicine. Co-authors of the study were Dr. Eugene Dong, a postdoctoral fellow, and Dr. Norman E. Shumway, associate professor of surgery.

The research was supported by grants from the American Heart Association and the U. S. Public Health Service.

- more -

The scientists studied 45 dogs with heart transplants. All grafts were done with the surgical technique originally developed by Dr. Shumway and Dr. Lower six years ago. The operation is now so successful that in a recent series of 32 transplants, all but three recovered from surgery and lived until the heart was rejected or the animals died from the toxic effects of the drugs.

"We now know how to give the drugs in the most crucial periods," Dr. Lower said. "The dog that is still alive represents our best achievement so far. There is no reason to believe that we won't do better and get longer survival."

He said that the long-term survivor is being carefully studied so that the researchers will know how well a transplanted heart can be expected to function in supporting circulation. They also want to know more about the long-term effects of the drugs. The drugs used are a steroid hormone, hydrocortisone or methylprednisolone, and azathioprine.

One serious problem which must be studied is the effect of rejection in producing muscle changes and scarring which could impair heart function. The surgeons reported that better drug treatment or better matching of the donor and recipient for genetic compatibility might help overcome this problem.

Dr. Lower declined to comment when the technique might be ready for trial on patients. "There is still so much to be learned from animal experiments that we are not ready to consider embarking on clinical trials," he said.

Note to Editors: This paper will be presented Thursday afternoon at the First Annual Colloquium of the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine at Stanford University School of Medicine. Theme of the meeting is "Frontiers in Mental Retardation." Among those attending will be R. Sargent Shriver, Peace Corps director and executive director of the Lt. Joseph P. Kennedy, Jr. Foundation, and Mrs. Eunice Shriver, executive vice president of the Foundation. See program mailed earlier for details.

FOR PM RELEASE THURSDAY, APRIL 1, 1965

Evidence of a possible link between mental retardation and toxoplasmosis, an infectious disease most frequently unrecognized clinically, was reported today by a research team at Stanford University School of Medicine.

Dr. Jack S. Remington, assistant professor of medicine, told the First Annual Colloquium of the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine that there are babies born with toxoplasmosis, but the disease is not detected because the infants look normal.

The babies who are born with the disease may grow up to be mentally retarded, possibly within three to four years, Dr. Remington said. The disease is presumably passed into the fetus by the pregnant woman.

"How a chronically infected mother can pass the organism to the child is not exactly known," Dr. Remington said, "but it has been demonstrated that laboratory animals with toxoplasmosis can bear offspring a year later which is also infected."

He said evidence that toxoplasma infection may be related to mental retardation was gathered recently in a study of mentally retarded children at Sonoma State Hospital. Blood tests performed on 350 children showed significant amounts of toxoplasma antibodies in 11 percent of them. The children had been selected after a review of their records which showed their retardation to be of unknown origin.

Another 400 children also were tested after their cases had been studied to rule out toxoplasma infection as a cause of mental retardation. These children, having genetic or other definable defects, were used for comparison purposes, Dr. Remington said. Only three percent of these tests were positive.

-MORE-

Dr. Remington's work, conducted both here and in El Salvador, is supported by funds from the Lt. Joseph P. Kennedy, Jr. Foundation and the National Foundation for Retarded Children. It is carried on cooperatively by the Stanford Medical School and the Palo Alto Medical Research Foundation.

Dr. Remington noted that up to now it had been particularly difficult to study the toxoplasma organism as a cause of mental retardation because of the high rate of toxoplasma antibody found in the normal population. He added that the second group of children in which antibody was low would provide a control or test group for his studies.

Toxoplasmosis is caused by a crescent-like organism the size of a blood cell which invades the tissues. The disease may occur congenitally, or may be acquired, presumably passed into the fetus by the pregnant woman. The disease may become chronic, assuming the form of cysts (particularly within muscle and nervous tissue).

When it occurs congenitally, the disease has recognizable symptoms. It may cause a stillbirth or a premature birth. It may end with the death of the baby or the illness may regress leaving the infant with varying forms of disability such as inflammation of the retinas or hydrocephaly, a defect producing in the newborn an unusually large head.

"It is estimated," Dr. Remington said, "that one in a thousand babies born in the United States has recognizable symptoms of toxoplasma infection. But how many more are born with the disease is not known."

He noted that a recent serologic survey he conducted in Palo Alto showed that among 600 women of childbearing age, 29 percent had the toxoplasma parasite. Similar tests conducted in El Salvador proved positive for 60 percent of women of childbearing age.

"We do not know how many of these women will pass on the organism to their babies," Dr. Remington said, "but the likelihood of a chronically infected woman giving birth to a child with mental retardation due to toxoplasmosis must be extremely small."

This can be shown by comparing the high prevalence of the disease among women in the normal childbearing population to the number of retarded children who have been found to have the organism.

"Still there are tests which can be used to find out if the child has the disease," Dr. Remington said. "If it is detected early it can be treated."

Dr. Remington issued a plea for requiring that a test for toxoplasmosis be performed in at least all young infants in whom mental retardation is found because with treatment further development of the retardation may be prevented.

He said that the hemaglutination test, developed five years ago by the National Institutes of Health, is a sensitive, reliable indicator of toxoplasma antibody in human or animal serums. In this test, sheep blood cells treated with tannic acid serve as the vehicle for measuring toxoplasma antibodies.

"Since we can detect the disease, these babies deserve to be treated," Dr. Remington said.

An American delegation on physiological development of the child under the chairmanship of Dr. Norman Kretchmer, executive head of the department of pediatrics of the Stanford University School of Medicine, will be travelling in the Soviet Union from April 5 through 28 to exchange medical and biochemical information with Russian colleagues.

The delegation was established under an agreement signed by the two countries in 1964 for exchanges in scientific, technical, educational, cultural and other fields.

During their stay the delegation will visit Russian institutes and schools in Leningrad, Moscow, Kharkov, Kiev and possibly Novosibirsk.

The delegation plans to exchange information on genetics, brain metabolism, physiology of the newborn and premature, infectious diseases, child development and endocrinology.

Other delegates are Dr. Alfred M. Bongiovanni, professor and chairman of the department of pediatrics at the Children's Hospital of Pennsylvania, Philadelphia, Pa.; Dr. Urie Bronfenbrenner, professor of child development and human relations at Cornell University, Ithaca, N. Y.; Dr. Donald Harting, acting director of The National Institute of Child Health and Human Development in Bethesda, Md.; Dr. Frederick C. Robbins, professor and chairman of the department of pediatrics at Metropolitan Hospital of Western Reserve University, Cleveland, Ohio; and Dr. Irving Schulman, professor and chairman of the department of pediatrics at the University of Illinois Research and Educational Hospitals, Chicago, Ill.

All the light in the world went out for Mrs. Betty Mantooth the day she was born. This was in 1924.

Although Betty wears two plastic eyes, she has resolved to live a normal life. And today, she is doing just that.

A wife and mother of two teenage boys, Betty works full time developing film for the Palo Alto X-ray department at the Palo Alto-Stanford Hospital Center, a job she has held since 1960.

Betty is happy with her work because she is doing something worthwhile for someone else. She takes X-ray films and puts them through developing and neutralizing solutions. Her husband devised Braille timers so she can time solutions to the exact minute. Sometimes she is so busy that she has four timers ticking at once.

During lunch hours Betty "reads" by listening to records. Right now she is making her way through a detective story entitled "Mother Hunt" by R. Stout. Each month she listens to the entire Reader's Digest and Holiday magazines. Her favorite stories are about the sea.

At home Betty does all the housework, although she hates it. She cleans, cooks and washes like anyone else. Her husband helps her pick out groceries each week.

Buying clothes is something she enjoys. She has no trouble telling if something fits, but she always asks the saleswoman if the color looks well with her black hair. She likes to wear red.

-MORE-

Her favorite pastime is lifting weights. Three nights a week she goes to a gymnasium for a workout, By touch she can tell the difference between the various size weights. At the gym she walks among the equipment because she has learned to "see" by listening to different sounds. To do leg raising exercises, Betty wears six-pound shoes which her husband made for her.

Her husband, who also works in the Hospital laundry department, refuses to get into a fight with her because "once losing in arm wrestling is enough."

Betty is a Californian. She was born in Fresno and has lived in Alameda almost all her life before she moved to Redwood City in 1960. When she was growing up, she attended the School for the Blind in Berkeley during the week. On weekends she played with the neighborhood crowd. She even took up horseback riding because she found a horse that could follow a group.

In 1943, Betty started training for airplane engine mechanics in Alameda. After two months of training, she transferred into the Naval Air Station proper to operate various machines like polishing lathes and buffing wheels.

In 1945 she married and became a full-time housewife until she started to work at Palo Alto-Stanford Hospital Center in 1960. Her vocational counsellor at the School for the Blind suggested she would make a good darkroom technician and introduced her to Mrs. Martha Chandler, darkroom technician of the Palo Alto Medical Clinic, who trained her for her present job.

Dr. Rachmiel Levine, a noted authority on diabetes, will deliver the nineteenth course of Herzstein Medical Lectures sponsored by the medical schools of Stanford University and University of California.

Dr. Levine, professor and chairman of the department of medicine at New York Medical College, will speak on April 5, 7 and 9 at 8:15 p.m. in the auditorium of the Medical Sciences Building at the University of California Medical Center in San Francisco.

Dr. Levine's three lectures are: Monday, April 5, Diabetes: Problems of Definition and Etiology; Wednesday, April 7, The Metabolic Lesions of Diabetes Mellitus, and Friday, April 9, Analysis of Some Theories of Insulin Action. The lectures are open to the public. Members of the medical profession, medical students, and other interested persons are invited.

Dr. Levine is president of the American Diabetes Association and has received its Banting Medal. He is a distinguished scientist, teacher and writer. He has published more than 200 papers in the fields of experimental and clinical diabetes, hormonal activity and metabolism of carbohydrates.

Dr. Levine received his B.A. and M.D. degrees from McGill University. He received his residency training in internal medicine from Michael Reese Hospital in Chicago.

From 1947 to 1960 Dr. Levine was professorial lecturer in physiology at the University of Chicago. In 1952 he became chairman of the department of medicine and director of medical education at Michael Reese Hospital. He joined the New York Medical College in 1960.

The Morris Herzstein Lectures are sponsored by the medical schools of Stanford University and University of California under an endowment from the late Dr. Morris Herzstein of San Francisco. Since its establishment in 1929, some of the world's leading medical scientists have shared their views with colleagues and the public.

NOTE TO CITY EDITORS AND SCIENCE WRITERS

On Thursday, April 1, the Stanford University School of Medicine will hold its First Annual Colloquium of the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine.

The theme of the colloquium will be Frontiers in Mental Retardation.

Among the guests will be R. Sargent Shriver, Peace Corps director and executive director of The Lt. Joseph P. Kennedy, Jr. Foundation; Mrs. Eunice Shriver, executive vice president of the Foundation; Dr. Frederick C. Robbins, Nobel prize winner in the study of virus diseases and chairman of the department of pediatrics at Western Reserve University, and members of the Foundation medical advisory committee.

The morning meeting will begin at 9 a.m. in Room M106 of the Medical School Building, and the afternoon session at 1 p.m. (A detailed program is attached.)

Among Stanford pacticipants will be Dr. Arthur Kornberg, Nobel prize winner in medicine and physiology and executive head of the department of biochemistry, Dr. Joshua Lederberg, Nobel prize winning geneticist who heads the department of genetics, and Dr. Norman Kretchmer, executive head of the department of pediatrics.

If your reporter, photographer or both will come to the information desk in the main lobby of the Stanford Medical Center, the clerk will direct them to the room.

Because of the tight schedule, no press conference is planned but the meeting participants will welcome questions from the audience.

Sandwiches will be served at 12 noon during recess in Room M125 in the Medical School Building.

Don D. Hamachek, administrative associate at the Baptist Memorial Hospital in Memphis, Tennessee, has been appointed associate director for finance for the Palo Alto-Stanford Hospital Center. His appointment was announced by Dr. LeRoy E. Bates, hospital director, and is effective April 23.

Mr. Hamachek will succeed Arthur J. Hoffman who resigned in January to accept the position of controller for Covina Inter-Community Hospital in Covina, California.

Mr. Hamachek has excelled in financial management and hospital computer system planning and development. In 1960 he installed a computer system at Baptist Memorial Hospital, the first in any hospital in the country. Because it operated so successfully, the hospital became the center for anyone interested in applying computers to financial management and data handling. He went on to apply it to medical record analysis and professional service statistics. He has been employed by that hospital since 1956.

Prior to that time, Mr. Hamachek was accountant and business manager for Passavant Hospital in Chicago, a position he held from 1952 to 1956. During that time he became active in the American Association of Hospital Accountants and served as president of the Illinois chapter in 1956. He also served as lecturer in hospital accounting at Northwestern University.

Recently Mr. Hamachek was appointed to an advisory committee for comprehensive managerial information for hospitals by the American Hospital Association and serves as a member of the Association's Accounting and Business Practices Committee. He is a member of the American College of Hospital Administrators and also holds a fellowship in the American Association of Hospital Accountants. He is past president of the Memphis Hospital Council and editor of the accounting column for SOUTHERN HOSPITALS magazine.

He and his wife have four children. The oldest son and daughter are attending the University of Mississippi where their son will graduate in June and enter Duke University to study hospital administration. The other boy and girl are teenagers.

The influence of steroids--hormones secreted by the adrenal cortex and sex glands--on the brain and behavior will be studied at Stanford University School of Medicine under a Public Health Service grant.

The award was announced today by Dr. Luther L. Terry, surgeon general of the Public Health Service of the U. S. Department of Health, Education and Welfare.

The School of Medicine will receive $142,730 in direct costs for the first year plus additional support totaling $789,499 for six years from the National Institute of Mental Health in Bethesda, Md.

The study will focus initially on the female sex hormone, progesterone. Dr. David Hamburg, professor and executive head of the department of psychiatry at Stanford, will head a team of psychiatrists, biochemists, psychologists and physiologists.

They will study the role that progesterone and the corticosteroids (hormones secreted by the outer area or cortex of the adrenal glands) may play in causing the emotional distresses of women during the menstrual cycle, pregnancy, and after childbirth.

Recent research suggests many close links between the steroids, brain and behavior. Dr. Hamburg and other scientists have found that marked changes in steroid hormone production often coincide with emotional disturbance. For example, they have found increased concentrations of corticosteroids in over-responsive persons.

Other studies have shown that the body's level of the female sex hormone, progesterone, decreases during premenstrual and post-pregnancy periods. These decreases may be related to emotional disorders of these periods which have ranged from premenstrual tension and depression to psychiatric hospital admissions, violence, and suicide attempts.

-MORE-

"It is well-known," Dr. Hamburg said, "that marked fluctuations of mood frequently occur in clear-cut correlation with the menstrual cycle of women. Typically the premenstrual period is likely to be a phase of increased irritability and depression.

"The phenomenon has naturally attracted considerable clinical attention but, despite the rather extensive documentation of these relationships, there has been little attempt to study the possible role of biochemical factors."

Dr. Hamburg and his associates plan a detailed study of the influence of different levels of progesterone on the brain and its consequent effects on normal and abnormal behavior.

Wives of married students at Stanford will be asked to volunteer for studies focusing on the menstrual cycle and the first pregnancy. The studies are designed to answer such questions as:

. How decreases in the female hormone, progesterone, affect premenstrual tension in different women?

. What is the relationship between hormone level changes in varying degrees of anxiety and depression in pregnant women?

. How are the brain and behavior affected by the sharp drop in progesterone following pregnancy?

. What pathways do progesterone and corticosteroids travel in the body?

. How does the body dispose of the metabolites (chemical by-products of progesterone)?

. How does progesterone affect the electrical activity of the brain? (There is considerable evidence that progesterone and its chemical by-products may have profound effects on the central nervous system such as producing certain sedative effects).

The investigators will also conduct sleep and dream studies to determine how changes in hormone levels affect sleep patterns, since there are indications that sleep abnormalities may contribute to psychological disorders.

Dr. Donald W. Seldin, a noted authority on metabolic diseases, will be a guest lecturer of Stanford Medical Center on March 17.

Dr. Seldin will discuss "Dearrangements in Potassium Metabolism and Acid Balance" at 8:15 p.m. in Room M106 of the Stanford Medical School.

Dr. Seldin is professor of internal medicine at Southwestern Medical School of the University of Texas in Dallas. He is a member of numerous societies, including the American Society for Clinical Investigation, the American Society of Internal Medicine, American College of Physicians and the Endocrine Society.

He graduated from the Yale University School of Medicine in New Haven, Conn. in 1943.

His lecture is sponsored by the Charles D. Armstrong Memorial program of the Palo Alto Medical Staff and the Palo Alto-Stanford Hospital department of medicine. Dr. Armstrong was a co-founder of the Menlo Medical Clinic and chief of staff of the Palo Alto Hospital in 1956-57.

During the day, Dr. Seldin will participate in informal discussions with members of Palo Alto Medical Staff department of internal medicine.

Hangover is a black cat. His name-to-fame didn't happen overnight from drinking too many martinis.

Hangover came to the Stanford Medical Center in 1961. Since that time Dr. F. Blair Simmons, assistant professor of surgery at the Stanford Medical School, has been observing him. Hangover has a hearing loss in the inner ear where the process of converting sound energy into nerve impulses begins.

Dr. Simmons, who specializes in disorders of the ear, nose and throat, hopes his research will show what kind of auditory information is necessary for Hangover to hear. "The information may possibly be applied to humans because a cat's inner ear is about the same size as the human ear," Dr. Simmons said.

"The only problem with Hangover is that he costs too much for room, board, hearing tests and drugs," added Dr. Simmons. Hangover has cost the Stanford Medical School about $4,000. It takes 25 hours to administer one hearing test on him.

"The same type of information we learn from Hangover could be obtained by studying human inner ear bones. One human would cost the Medical School only $150," according to Dr. Simmons.

But Dr. Simmons is using Hangover because he has not been able to get enough people with impaired hearing to volunteer for research on the deaf. The ultimate prevention of most deafness depends, to a large extent, on having available for research the organs which cause the deafness.

These organs are the bones of the inner ear. But the problem in research is that the inner ear cannot be seen or directly examined during life because of its inaccessible location within the temporal bones, the hardest bones within the head that surrounds the inner ear bones and their nerve structures.

Stanford Medical Center is taking part in a program sponsored by the Deafness Research Foundation. The Foundation is seeking people who wish to donate earbones when they die to bone banks. These bones will be used in research toward aiding other deaf persons with potentially repairable hearing defects.

The purpose of the bone bank is to provide the necessary channel through which individuals may bequeath their inner ear structures. And they are the greatest value when submitted with the results of hearing tests and other available pertinent medical records.

Then such tests that had to be made on Hangover would not be necessary.

"Why Some Children Can't Read" is the subject of a panel discussion Monday (March 8) on Doctors News Conference, KTVU, Channel 2, at 9:40 p.m.

Dr. Jon Eisenson, professor of speech pathology and audiology at Stanford University School of Medicine, will appear on the panel. He is also director of the Scottish Rite Institute for Childhood Aphasia at Stanford, and advisor to the California Easter Seal Society and United Cerebral Palsy Society.

Also appearing on the panel will be Dr. Douglas L. Crowther, assistant professor of neurology and pediatrics, University of California School of Medicine. The program moderator is Dr. Hayes Newby, director of speech pathology and audiology at Stanford.

The discussion will be concerned primarily with a special type of reading problem called dyslexia -- its symptoms, causes and treatment.

Technicians in lipid research at Stanford Medical Center may be using a hair dryer, but they aren't drying their pincurls.

What they're really doing is drying liquid plasma extracts in thin layer plate chromotography, a technique for separating sugar from other blood plasma ingredients. Doctors in lipid research study the affect of diet, hormones and drugs on fat metabolism.

"The hair dryer is an indispensable piece of equipment," says Mrs. Rosemary Hess, the technician who purchased it for $9.

"We have to dry many layers of an extract on one plate. Waiting for each layer to dry takes too long," she said. The dryer is a time-saving device for alcohol and water solutions which evaporate slowly. For ethers which dry more quickly, however, the hair dryer is not necessary.

In addition, quick drying prevents the extract from spreading over too much of the plate's surface. By using the dryer, the technicians are able to dry the extract in a very narrow band.

Mrs. Hess said she searched everywhere for a "hood-less" dryer. This type, which can be held in the hand or set on a post, has almost been replaced on the market for the dryers which come with a hood. Today women just don't want to be bothered drying each pincurl individually. But the dryer is perfect for Mrs. Hess and others in the lipid research department.

"And it's a lot less expensive than the dryers with the hood," she added.

Persons undergo a personality change when they are deprived of their dreams, an investigator from Stanford University School of Medicine reported today.

Dr. William Dement, associate professor of psychiatry, said "we are not yet certain how far out of hand this can get, but we suspect that such a disturbance can play an exaggerated role in those people who are susceptible."

Dr. Dement described his studies in an article in the University magazine, STANFORD TODAY.

He said he had devised an experiment to find out what happens if a person maintains his normal hours of sleep, but is not allowed to dream.

By using earlier findings which showed that dreaming periods were precisely related to rapid, almost flickering eye movements, Dr. Dement stuck tiny electrodes on each side of volunteers' eyes and carried the leads to a brain wave machine (electroencephalograph) in the next room.

Dr. Dement awakened his volunteers whenever the brain wave machine indicated they began to dream. He allowed them to fall asleep again. And so on, night after night for up to 15 days.

By the third night, most volunteers began to act edgy and strange, Dr. Dement reported. They got hungry, anxious and irritable, had difficulty concentrating, and displayed very impulsive desires to do things they ordinarily would not consider.

In the final part of the experiment, when they were allowed to sleep as long as they wanted, the volunteers dreamed up to four times as much as usual, depending on the length of the deprivation.

-MORE-

Similar results were obtained from dream deprivation tests made on cats for 70 days. Several of them developed ravenous appetites, exhibiting a continuous, restless searching for food. Exploratory behavior in general was enhanced. And behavioral peculiarities appeared such as ceasing to groom and hypersexuality. Several of the cats tested showed signs of impaired learning. Again dream deprivation in the cats led to an intensification of the phenomenon.

Why does the body apparently require dreaming time and build up a strong compulsion to dream when deprived of it?

Dr. Dement speculates there may be a biochemical explanation. The effect of dream deprivation is such an orderly process that it is impossible to escape this conclusion, he said. Perhaps dreaming, when it is occurring normally, engenders periodic changes in brain metabolism, allowing certain biochemical adjustments to be made. In this way neural functions are kept in proper balance.

In the absence or restriction of dreaming the biochemical status of the brain shifts in the direction of increased excitability, which probably leads to personality changes, Dr. Dement said.

Working on a hunch that there may be important links between dream deprivation and certain forms of mental illness, Dr. Dement and his collaborators are now directing a major portion of their research along this line.

He said that in the illness of schizophrenia, for example, the individual involved usually has had a poor life experience, is incapable of dealing with the world around him, and is prone to devastating anxiety.

Either as the result of a gradually deteriorating process or sudden stress, such a person enters into a state of chronic anxiety. This anxiety leads to insomnia and specifically to a loss of dreaming. There is even evidence that anxiety alone, unattended by insomnia, may suppress dreaming.

Thus, it is the interference with sleep that is important, not anxiety alone, Dr. Dement said.

Editors: This story supplements a release mailed earlier by the University of California Medical Center. It provides additional information on how the technique of treating hyalin membrane disease was applied to the first patient in this country.

FOR RELEASE APRIL 30, 1965

Some 50,000 infants suffocate each year in the United States alone. The infants, most of them premature, turn blue and choke and die.

They die from something that is not to this day in most current medical directories, dictionaries or guides. It is a mysterious condition called hyaline membrane disease. Almost two years ago, this disease killed Patrick Bouvier, the younger son of the late President John F. Kennedy, and it usually kills about half the infants it strikes.

Both the cause and cure of the trouble have been heart-breakingly elusive. There are many complicated theories about how hyaline membrane disease blocks the lungs.

But a promising lead has emerged from a strange and circuitous research path blazed by a team of American and Malaysian doctors in Singapore last summer. In the busy maternity ward of the big Kandang Kerbau Hospital, these doctors tested a technique that may result in a more effective treatment of the babies in respiratory distress.

The results of this study were published today in the May issue of PEDIATRICS by Dr. John Clements and Dr. William H. Tooley of the University of California, Dr. Marshall H. Klaus, assistant professor of pediatrics and director of the Research Center for Premature Infants at Stanford Medical Center, and their associates, including Dr. Josephine Chu of Cleveland's Mt. Sinai Hospital, and Dr. M. A. Thomas, of the University of Singapore medical faculty.

These pediatricians now believe that the basic cause of the deadly breathing impairment is a constriction of thousands of small artery branches which carry blood to the lung's air spaces to pick up oxygen. They also blame a collapse of those air spaces.

"We think," the investigators reported," that this collapse results from a nerve reflex which is very active in the unborn infant, one that has been studied but has never before been demonstrated in human infants. It is a protective centralizing reflex."

-MORE-

It is well known that in certain diving animals such as seals, this reflex causes blood to be temporarily diverted from less important organs in order to send more to the heart and brain. This way the animals can conserve oxygen and prolong their stay underwater.

"In the human this reflex can come into play when the blood of the fetus becomes low in oxygen," Dr. Clements and Dr. Klaus said. "This could occur if the mother herself suffers from oxygen lack, if she has low blood pressure, or if there has been an interference with the placental circulation--a constriction of the umbilical cord, for example. What happens then is that the centralizing reflex shuts down the blood flow to the lung and kidneys and intestines and increases the flow to the heart and brain.

"The centralizing reflex makes sense in the unborn infant, whose lungs are not yet breathing air and who is getting all the oxygen from his mother through the placenta. But if the reflex goes into action after the baby is born a shut-down of the lung's circulation is dangerous, even disastrous."

Convinced that the artery constriction was an important part of the respiratory distress problem, the doctors in Singapore sought a way to counteract it. They chose a powerful nerve hormone called acetylcholine. This is a chemical naturally released at the ends of certain involuntary nerves and it is responsible for many bodily reactions--sweating, flushing, and most important in this problem, dilating lung blood vessels. Because acetylcholine is rapidly neutralized in the body by an enzyme, cholinesterase, it was necessary to give it to babies through a thin plastic tubing passed through the umbilical vein directly to the lung.

Of 12 babies treated with this method, 11 responded promptly and favorably.

Since their return from Singapore last August Dr. Klaus has continued the acetylcholine studies at Stanford Medical Center, and Dr. Clements and his associates at the University of California have been making a detailed analysis of the Singapore results.

One of the first babies to successfully receive the treatment in this country was Robert Edmond Speirs, son of Mr. and Mrs. Robert Speirs of 1104 Moffet Boulevard at Mountain View, Calif.

The baby was born in the Palo Alto-Stanford Hospital Center one month prematurely. At birth he was blue and struggling for breath, with a characteristic grunting and chest retraction. He appeared very sick, said Dr. Klaus, when the acetylcholine was started. But over the next six to 10 hours the baby's breathing returned to normal limits, and after 24 hours of treatment the continuous infusion of the drug was stopped.

The respiratory rate of the baby rose rapidly, he remained pink and breath sounds were good so the doctors decided not to restart the infusion. Nine days later, he left the Hospital and he is now a healthy 20-pound baby.

"It should be pointed out," Dr. Klaus said, "that in the future acetylcholine may not be the drug of choice in the treatment of respiratory distress, but it has been helpful in elucidating what may be the major underlying cause of the disease."

An additional grant of $10,000 to the Palo Alto-Stanford Hospital Center for the care of needy handicapped children was announced today by the California Elks. This grant brings the Elks total contribution to the Hospital to $35,000 for the current year.

"The Elks were pleased to aid almost 100 children from 20 counties in California with last year's grant of $25,000," said John Morey of Menlo Park, Elks treasurer. "With the additional grant this year, we look forward to even greater accomplishments."

Children who receive help from the Elks grant include those suffering from defective hearts, blood disorders, asthma, kidney disease, eye conditions, speech problems and orthopedic handicaps. Others, who fail to grow normally, or who have emotional problems associated with handicaps, are also aided.

The grant pays for laboratory tests, treatment, surgery, medicine, transportation and even housing expenses for parents from out of town if they need it to stay here while their child is hospitalized. Those receiving aid are recommended by physicians and screened by social workers at the Hospital.

Giving Dr. Frank C. Winter an engraved gold medal was how 100 villagers in San Jose del Cabo said thanks for having their sight restored.

Two weeks ago, Dr. Winter, acting chief of the division of ophthalmology at the Stanford University School of Medicine, made his sixth trip to the isolated village at the tip of Baja, California. Touched by his mission of restoring sight to over 100 people, the villagers presented him with a gold medal inscribed in Spanish: "Con Gratitude Dr. Winter".

"I was so overwhelmed that I couldn't say anything. But the villagers understood," said Dr. Winter.

Dr. Winter has performed over 100 operations for cataracts and other disorders. He has prescribed glasses for hundreds of partially sighted people and later supplied them with glasses which were donated by Parsons Optical Company in Palo Alto.

Dr. Winter did more than help persons who needed medical services. He made friends for America by living with the people.

Senor Adolfo G. Dominguez, Mexican Consul General in San Francisco, helped to make Dr. Winter's trips possible. The Governor of the province, General Salinas Leal, has given Dr. Winter permission to perform his medical work. The district medical officer, Dr. Eduardo Rodriguez, publicizes Dr. Winter's coming so the people can come from the nearby villages by mule or truck to receive treatment at the simple 40-bed hospital in San Jose del Cabo which is operated by six nuns.

"When I arrive, the people are waiting for treatment. A village assistant helps me line them up. Then I check them for blinding conditions that can be cured by surgery."

-MORE-

One of the most remarkable phases of Dr. Winter's visit was the treatment of a nine-year-old boy. He was blinded in his right eye by a stick as a baby. What sight he had from his left eye was in great danger, due to an open sore in the cornea, the transparent part of the eye which covers the iris and admits light.

"In America he would have had an emergency operation immediately, but the general practitioners in Baja have not had the chance to specialize in eye work. Since there were no fresh corneas available for transplant when I first saw the boy last year, I fashioned a temporary patch by using tissue from his blind eye. This covered up the dangerous hole and temporarily saved the eye. But to restore the sight, a clear corneal graft was necessary."

Before leaving on his recent trip, Dr. Winter activated "The Stanford Eye Alert" for a fresh cornea which he could transport to Baja. Accompanied by Dr. Richard Yukins, fellow in ophthalmology at Stanford University School of Medicine, to assist him, and James Duncan, owner of a flight school in Palo Alto, he flew down and successfully completed the operation.

Under "The Eye Alert" system, eyes are obtained from people who die at the Palo Alto-Stanford Hospital, the Palo Alto Veterans Administration Hospital and the San Mateo County General Hospital. The admitting office, nursing office and emergency room are alerted to notify the Hospital's resident in ophthalmology on duty when a patient dies. If the eyes are in good condition, he then talks to the patient's family and secures permission to use the eyes in transplant surgery. Thus, invaluable eyes are often available within hours after "The Eye Alert" is put into effect.

FOR RELEASE MONDAY, APRIL 26, 1965

CINCINNATI -- Cell surgery, artificial limbs that feel, chemicals for welding wounds, transplantation of whole organs and other new, bold techniques for saving and prolonging human life may be possible within our own lifetime, a Stanford University professor said Sunday.

Dr. Robert Chase, executive head of the department of surgery of the School of Medicine, made this prediction as he described the brave new world of surgery at the 1965 Stanford Conference here.

He said he envisioned in the not too distant future the development of a new specialist, the ultra micro surgeon whose work would be confined to cellular and subcellular surgery.

"Blood vessels and nerves of very small caliber are already being repaired through dual microscopes with material that can barely be seen with the naked eye," Dr. Chase said.

"In the field of wound healing," Dr. Chase continued, "it is quite clear that man will ultimately be able to chemically weld wounds."

Fractures will be instantaneously repaired by restoration of full bone strength without the necessity of the long period of immobilization. And infections in wounds would be unheard of.

The mysteries of diagnosis and designs for treatment will be largely computerized in the modern hospital of the future.

"Imagine entering the hospital of 1984," Dr. Chase told the audience. "Your medical history will be taken and fed directly to a giant computer which will return the diagnostic possibilities in order of likelihood. Your examination will employ a myriad new, sophisticated laboratory and special techniques such as recording of heart beat, blood pressure, gastrointestinal activity and other functions on electronic tape for replay into the diagnostic computer."

-MORE-

One of the great accomplishments of the future, Dr. Chase predicted, would be a solution to the problem of transplantation of whole organs or parts from one individual to another, opening up a new era in the treatment of disease.

He said presently one of the more famous Stanford personalities is "Ralphie," a dog who has gone for nearly one year with a totally transplanted heart from another dog.

"If it can be done once," Dr. Chase said, "it can be done again and with predictable success once the ideal method for avoiding immunologic rejection can be achieved."

With transplantation, man will be able to control other organs as well, like the thyroid, pituitary and sex glands with ultimate goal the alteration of aging process.

"I have little doubt," Dr. Chase said, "that cancer and other new growths will come under control within the next two decades while research in neurology and anesthesia will give rise to some form of reliable electrical 'consciousness control' without the time requirements and side effects of today's drug anesthesia techniques."

Dr. Chase said that the laser beam, although still in an experimental stage, will have a place in the medicine of the future. Its possibilities in getting at disease at various depths in the body without the usual surgical dissection appear to be innumerable.

"The same may be said for the stereotactic techniques already in use for the treatment of central nervous system disorders," Dr. Chase stated. These techniques allow surgeons to probe the inner reaches of the brain with extreme precision for selective destruction of diseased or abnormally functioning units.

"The nature of research in our own laboratory at Stanford makes it logical to predict that within the next decade electronic substitutes for the hearing apparatus will be perfected," Dr. Chase said.

"Mechanical implants for direct stimulation of the hearing and auditory nerve are already functional in cats," he reported. "It takes little imagination to expand this idea to electronic substitutes for the photosensitive eye with direct stimulation of the optic nerve in people who are otherwise doomed to total blindness. Tactual sensation may also be fed into the central nervous system from electronic devices.

"We may thus develop artificial limbs with the ability to feel."

But while Dr. Chase is confident that man could turn these awesome and exciting possibilities into reality, he said he was "far less certain of our capacity to comprehend the human responsibilities involved in the brave new world of surgery."

"We are now faced with the decision, who shall live and who shall die." Can this decision be placed on the medical profession? The sociologists or religious leaders? Dr. Chase asked.

He said that surgeons are already confronted with this problem arising from the sacrifice of a kidney from one family member or voluntary donor to use in a sick recipient. While such transplants will significantly lengthen the survival for the recipient, statistics show no permanent survivors following kidney transplantation except in identical twins.

"Most assuredly," Dr. Chase concluded, "the dilemmas we now face will be geometrically compounded with the predictable breakthroughs in medical science."

"How can I be sure I get the right baby?"

This is one of the many questions that prospective mothers ask on the twice monthly maternity tours of the Palo Alto-Stanford Hospital Center.

"We have never had a mixup," said Mrs. June Thompson, director of delivery rooms. "We use a foolproof tag system. Before the mother and baby leave the delivery room, a nurse puts a plastic identity band with the mother's name and a code number on the mother's wrist and two on the baby's wrists. These are not removed until mother and child have left the Hospital."

Since the Hospital opened in 1959, almost 3,000 people have taken maternity tours. They come from as far away as Half Moon Bay to Fremont and as far south as Gilroy. In groups of about 20, the prospective mothers, fathers, and even grandmothers are shown around by a volunteer Pink Lady or Gray Lady who has been trained for the job.

The maternity tours start in the main lobby at 11 a.m. on the first and third Wednesdays of every month and take about an hour. The first stop is the emergency entrance, where all maternity patients are admitted.

"Make a trial run, preferably at night," the prospective parents are advised, so there will be no panic about finding the right place when the baby is on its way!

The tour then goes up to the waiting lounge on the third floor, so the husbands can see where they will be pacing the floor or watching TV. Next the group goes into the labor and delivery areas, where Mrs. Gertrude Schweitzerhof, head nurse, explains the procedure and shows the husbands the gowns they must wear if they wish to stay with their wives during labor.

-MORE-

"Almost all husbands choose to be with their wives whenever possible," Mrs. Schweitzerhof reports. "They must scrub and wear gowns to keep the area as sterile as possible as a protection for the mother."

Next the tour goes to the delivery room exit, from which the new mother and baby will emerge, and the mother will announce whether it's a boy, a girl, or both!

The group then views the rooms where the mothers will stay after delivery, and Mrs. Mary Sunnergren, head maternity nurse, explains the routine for mother and child while in the Hospital. The next stop is the Solarium where a question and answer session is held.

Some points of information and advice that Mrs. Sunnergren frequently gives are:

"Children under 16 cannot visit in the maternity section. Don't let your husband bring your little ones outside and wave and shout from the window. It is much better to talk to them by telephone. There are phones in every room.

"The Hospital averages about 200 births a month now, with peak months like September and May running as high as 250.

"For foreign mothers who have difficulty with English, advance arrangements are made for a translator, usually a relative or friend, to be with her. The department also has a file of personnel who speak various languages and can be called in case of an emergency."

On the way out, the tour stops by the nursery window to view the newest arrivals. Many persons on the tour will be back in a few days or weeks.

"I recognized so many friendly faces that I felt right at home!" declared one young mother. "When I had to rush back for an early delivery, I wasn't scared to death as I might have been."

Prospective parents are urged to take the maternity tour at least a month before their baby is due. Reservations must be made by calling ext. 5594.

FOR FURTHER INFORMATION CONTACT: Samuel Moffat (DA 1-5310)

Note to Editors: For release at 1 p.m. on Tuesday, April 13, 1965. Dr. Pool will be staying at the Ambassador Hotel in Atlantic City should you wish to contact her.

ATLANTIC CITY, April 13--A new technique for extracting the blood fraction needed to prevent bleeding in hemophiliacs was announced today by two researchers from the Stanford University School of Medicine.

The method is so simple it can be carried out in any blood bank or hospital without special equipment. Once the fraction has been removed, the rest of the blood is available for use in regular transfusions.

The fraction is 15 times as concentrated as in normal blood plasma. This means that a hemophilic patient need not be given whole plasma which includes a great deal of liquid that overloads the body's circulatory system.

The technique was reported today at the 49th annual meeting of the Federation of American Societies for Experimental Biology.

Authors of the report were Dr. Judith G. Pool, a senior research associate at Stanford, and Mrs. Angela E. Shannon, a research assistant.

The extract may be dissolved in a small amount of sterile salt solution before administration so that it provides 15 times the concentration of antihemophilic globulin (AHG) in plasma for a given weight of protein, Dr. Pool said. While commercial preparations of AHG are available, these are only about three times as concentrated as plasma and are quite expensive.

The fraction is prepared by drawing blood in double bags now widely used by blood banks. The bag with whole blood in it is spun in a refrigerated centrifuge to separate the cells from the plasma.

-MORE-

Next, the plasma is squeezed out of the first bag into the second. Then the plasma bag is immersed in a mixture of dry ice and acetone for a few minutes to quick-freeze the liquid.

When the plasma is frozen solid the bags--still connected together by plastic tubing--are both placed in the refrigerator. Twenty-four hours later the plasma will have thawed, leaving a cold-insoluble precipitate. The bags are then re-spun to bring the precipitate to the bottom. The plasma is drained back into the bag with the cells to reconstitute the whole blood.

Bags with precipitate in them may then be frozen and stored until the AHG is needed for a patient. Activity of the AHG will last for weeks or months.

Dr. Pool has tested the effectiveness of the stored AHG with an improved clotting assay method she developed six years ago. Frozen AHG is now being accumulated at Stanford Medical Center for use by hemophilic patients in the near future.

Hemophilia is a rare hereditary condition found almost exclusively in males. Victims of it lack one of the nine or ten plasma proteins responsible for making blood clot. Patients are very susceptible to injury, but more often bleeding occurs spontaneously, particularly in the joints of the legs and arms. As a result, boys with the condition are often crippled by the time they reach adolescence.

Editors: For p.m. release Tuesday, April 13, 1965. Drs. Rosan and Glick will be staying at the Mayflower Hotel should you wish to contact them.

ATLANTIC CITY, April 13 -- The powerful light of a laser beam has been used to study the distribution of minerals in the stomach of man and experimental animals, two researchers from Stanford University School of Medicine reported today.

Dr. Robert Rosan, assistant professor of pathology, and Dr. David Glick, professor of pathology, described the newest application for the laser to the annual session of the Federation of American Societies for Experimental Biology in Atlantic City.

The Stanford investigators said they found at times more calcium and magnesium in the surface cells of the stomach of children than in the deeper cells or in the mucus which the stomach secretes. In adults the pattern of the minerals was reversed.

Until now the distribution of these minerals in stomach cells was unknown.

"We do not understand the significance of calcium and magnesium in the stomach," the researchers said, "but it may be related to the control of secretion of gastric juices."

This was the first time that such a study in samples as small as 30 millionths of an ounce has been performed, and the elements were measured in about one-thousandth of the sample, they said.

The amazing electronic device--which emits light in a brilliant, narrow beam--is focused through a microscope on a spot of tissue, sliced to thickness of one-thousandth of an inch, and frozen to prevent the minerals from diffusing.

Packing energy of about 18,000 degrees, the beam vaporizes the tissue instantly. The vapor literally rockets between electrodes which set off a spark, and the gases form a characteristic spectrum or rainbow on a sheet of film. The lines represent each chemical in the tissue.

-MORE-

"From the film each element can be recognized and measured with an error of less than 10 percent in a properly regulated laser," the researchers said.

To have a simple standard for comparison, the scientists mount the tissue slices on ordinary photographic film. The laser penetrates the film as well as the tissue, and the amount of silver vaporized from the film is used as a basis for comparing the measurement of the other elements.

Ten or more elements can be discovered from this simple, quick operation, Drs. Rosan and Glick said. The procedure takes less than a second and requires very small tissue samples. The same analysis with conventional tests requires 20 to 30 minutes for each element.

The technique may be ideal as an adjunct to other tools in diagnosing illness, where presence of certain elements are a tip off, the researchers said.

Dr. Rosan and Dr. Glick said they plan to extend their study to effects of various physiological states, and might do this in part on the living stomach wall. They have already applied the laser on living persons without pain or harm obtaining a direct analysis of skin, teeth and hair.

The type of equipment used in the Stanford experiments is a laser combined with a conventional spectrographic device. It was developed by Frederick Brech of the Jarrell-Ash Company of Waltham, Mass. The laser beam is produced by exposing a synthetic ruby to an intense flash of light generated by millions of watts of energy.

A more efficient system for storing nitrous oxide, an anesthetic known as laughing gas, has recently been installed at the Palo Alto-Stanford Hospital. Although the system is common in industry for charging whipped cream dispensers, it has not been installed in any other hospital in the country.

The system consists of one large cylinder or bulk unit containing about a three months' supply of liquid nitrous oxide. It replaces a system of 19 smaller cylinders requiring an operator to change the cylinders every two or three days.

"The new system is self-operating," said Dr. Grant Fletcher, medical director of the department of inhalation therapy. "When the supply of nitrous oxide gets low, a tank truck comes to the Hospital to refill the cylinder without shutting down the equipment or patient care."

The bulk unit has a control system which maintains the liquid at a constant temperature and pressure. The liquid nitrous oxide sits in the bottom of the cylinder like water in a basin. Gaseous nitrous oxide forms above the liquid. The pressure in the tank forces the gas into a pipeline connected to the Hospital's 14 operating rooms and four delivery rooms. As the gas is drawn off the top of the liquid, additional gas is formed by evaporation.

In the previous system, common in most hospitals, the 19 cylinders fit into a central pipeline called a manifold. Each 200-pound cylinder has to be lifted and attached to the manifold manually.

A common problem was ice forming on cylinders and pipelines when the Hospital used high amounts of the anesthetic. The chilling dropped the pressure in the cylinder and made them inoperative. This reduced the supply of nitrous oxide available for the operating and delivery rooms.

To maintain a safe supply level it was often necessary to attach a new full cylinder and discard the partly filled frozen cylinder. Freezing does not occur in the new bulk unit because the liquid is kept at a constant temperature and pressure.

A continuous supply of the gas is necessary for the Palo Alto-Stanford Hospital because 200 liters of nitrous oxide must be piped into the operating rooms at peak times, according to Dr. Fletcher. The new system has the capacity to send off 800 to 1,000 liters.

The Hospital has a contract with Ohio Chemical Co. in Richmond, California, who paid for the unit and installation. The Hospital buys over 1.5 million gallons of nitrous oxide from them each year.

Editors: For release 1 p.m. Saturday, April 10, 1965. Dr. Aschheim will be staying at the Traymore Hotel in Atlantic City should you wish to contact him.

ATLANTIC CITY, April 10 -- Scientists and laymen have known that old age induces changes in the body, including the skin which becomes wrinkled and rough and loses its flexibility.

But how these changes occur is a mystery and a subject of much speculation and controversy among researchers.

Today several hundred of the nation's physiologists met in Atlantic City at the annual session of the Federation of American Societies for Experimental Biology. They heard a report suggesting that the phenomenon of aging may be occurring partly due to "inadequate traffic of nutritional substances across vascular membranes."

It was from experiments of how small molecules such as water and large molecules such as proteins travel in inflamed skin that the suggestion and the technique to study this phenomenon were born.

In inflamed skin, vessel membranes become more permeable and make it possible for scientists to observe how various substances filter through compared with normal skin.

The study was done by Dr. Emil Aschheim, assistant professor of dermatology and physiology at Stanford University School of Medicine.

Dr. Aschheim injected protein in rats with inflamed skin. The protein had been previously labeled with a special dye called Evans blue. Since the dye combines with the protein, blueing of the skin indicates that the vessels have become permeable to blood proteins and that these leak out into the tissue.

He repeated the experiment using radioactive proteins together with radioactive rubidium which tags blood flow. By monitoring the radioactivity in the inflamed and normal skin, Dr. Aschheim was able to measure accurately the protein inside and outside the vessels and relate it to blood flow of the skin.

From these studies, Dr. Aschheim determined that transport of large molecules across the walls of blood vessels depends on blood flow. In the inflamed skin, vessels let protein out very fast at a speed proportional to the blood flow similarly to the way water is transported in normal skin. But blood proteins leaked out slowly in normal skin.

This is believed by Dr. Aschheim to be an important regulatory mechanism which sets the conditions under which water and food substances are exchanged between blood and tissue.

"It is not inconceivable," Dr. Aschheim said, "that as we age, there is progressive deterioration of the internal environment, mainly because of decreasing traffic of nutrients across vascular membranes. This deterioration could affect the performance of various organs and thus contribute to aging."

What influences the ability of vascular membranes to transfer food from the blood as the person ages is not known. Dr. Aschheim believes that further research is needed into the problem of nutritional exchange between blood and tissue.

The chances of getting an eye infection from bacterial contamination of contact lenses may be less if the lenses, when not in use, are kept in a dry case rather than a wet one, reports a research team at Stanford University School of Medicine.

Dr. Margaret F. Obear, former resident in ophthalmology, and Dr. Frank C. Winter, acting chief of the division of ophthalmology, found that the storage solution is one factor that produces a media which allows bacteria to grow in the contact lens cases.

"No method of storage will completely eliminate all bacteria," Dr. Winter said. "Contact-lens wearers' other habits of using, wetting, cleaning and storing can also contaminate the cases."

After seeing in contact-lens users two occurrences of corneal ulcer due to pseudomonas bacteria, a dangerous organism, the researchers made a study of the storage cases of 80 patients. These patients had been fitted for contact lenses, and had received their instructions and prescriptions from ophthalmologists who did not know which patients were used in the study.

After several months of wearing contact lenses, cultures were taken of the patients' contact lens storage cases, and submitted to laboratory analysis.

Results showed bacteria present in both the wet and dry cases. However, dangerous organisms, such as pseudomonas bacteria, were recovered from wet cases twice as often as from dry cases, and other organisms were found in some of the wet cases but not in dry cases, according to Dr. Winter.

Since these bacteria can ultimately contaminate the lenses which are then placed in a person's eyes and may produce an eye infection, Dr. Winter and Dr. Obear recommend using contact lens solutions for washing and cleaning the lenses, but not for storing them. They suggest the following procedures both for inserting and storing lenses:

For insertion, first wash hands with soap and water and then remove lenses from the case. Wash the lenses with wetting solution and rinse them well with running water before placing them in the eyes.

For storing, wash the hands before removing the lenses from the eyes. Then wash the lenses with wetting solution, rinse with running water, and dry with a fresh disposable tissue. Store the lenses in a covered dry case.

As an extra precaution, clean the case every three days with a detergent and toothbrush, rinse the case well with water, and then dry it.

Dr. Robert C. Rosan, assistant professor of pathology at Stanford University School of Medicine, has received a three-year grant of $30,000 from the Lederle Medical Faculty Awards Program.

Under the award Dr. Rosan wants to stress molecular and biophysical aspects of pathology in teaching and hopes to refine his experimental interests in hormone control of glycoprotein secretion and divalent cations. He and Dr. David Glick, acting head of the department of pathology at Stanford University School of Medicine, hope to develop a laser spectroanalysis for quantitative histochemistry.

Lederle Laboratories Division of American Cyanamid Company, through a committee of outstanding medical educators, allocates $250,000 annually for grants to approximately a dozen young medical educators who give promise of continuing in full-time teaching and medical research.

The program, now in its twelfth year, has contributed to the support of 178 full-time faculty members of 66 medical schools in the United States and Canada for periods of one to three years.

Dr. Rosan graduated magna cum laude from the University of Colorado in 1952 with a B.A. in biology and chemistry. In 1957 he received his M.D. from Albany Medical College in Albany, N. Y. Dr. Rosan was a resident and fellow at Boston Children's Hospital Medical Center and Boston University Medical Center. He completed his training in 1962.

Dr. Rosan was appointed assistant professor in pathology at Stanford in 1963.

Dr. Rosan has had over 20 papers and several abstracts published in professional textbooks and journals. He is a member of numerous societies, including the Histochemical Society, the Society for Cell Biology, the American Association for the Advancement of Sciences and the Federation of American Scientists.

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos (DA 1-5310)

Editors: This story was transmitted on Business Wire April 1, 1965.

A mother who has a child with Down's syndrome or mongolism risks a greater chance of giving birth to a second affected child if she is 29 or younger, a Stanford Medical School investigator reported today.

"But only a part of the increased recurrence risk may be due to her transmitting an abnormal chromosome," Dr. Luigi Luzzatti, associate professor of pediatrics and preventive medicine, told the First Annual Colloquium of the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine here.

"There are other still ill-defined factors that may predispose to a recurrence of affected children in these mothers," Dr. Luzzatti said.

Down's syndrome is an abnormality affecting one child in every 650. Each child afflicted has an extra chromosome number 21. Most cases occur following faulty separation of chromosomes during formation of the female egg or the male sperm. Others are characterized by a fusion of the additional chromosome number 21 to another chromosome.

This type of the disease can occasionally be transmitted to a child by a mother who carries this abnormal chromosome, though she is a perfectly normal individual.

Dr. Luzzatti said that he and his collaborators studied 277 children with Down's syndrome. They determined first, how frequently affected children had inherited the abnormal chromosomes from the mother and second, the significance of this inheritance in young mothers giving birth to affected children after their first one was born with the disease. The children in the study were born to mothers 15 to 20 years of age.

-MORE-

Findings showed that the incidence of the disease as a result of faulty separation of chromosomes in the egg or the sperm was 92.1 percent, while the incidence of the fused chromosomes was 7.9 percent. In only 1.8 percent of the children, the normal mother had transmitted the abnormal chromosome to her affected offspring.

Dr. Luzzatti calculated that the risk of a mother 15 to 29 years of age having a second baby with Down's syndrome purely on the basis that she may carry the abnormal chromosome was 9.4 times greater than that of mothers in the general population. The risk for mothers 30 to 35 was 4.2 times and for those beyond 35 no increased risk was evident.

Comparing these figures with those already available defining the increased recurrence risk of these mothers, it appears that there are other causes predisposing to a recurrence, once the presence of the abnormal chromosome in the mother is ruled out, Dr. Luzzatti said.

"For purposes of genetic counseling," Dr. Luzzatti said, "when chromosome analysis in the affected child and the parents demonstrates that the abnormal chromosome is present in the mother, the recurrence risk for the children is well defined.

"If the mother does not have the abnormal chromosome, the risk of giving birth to a second affected baby is still slightly greater than that of the general population, but it is very small."

He added that more information is necessary on other factors that may control such recurrences to help parents understand the consequences of having more children.

Dr. Luzzatti's work is supported in part by grants from the Lt. Joseph P. Kennedy, Jr. Foundation and the John A. Hartford Foundation.

Nurses caps tell a story!

Every school of nursing throughout the entire world has its own distinctive cap awarded at graduation and worn by its graduates ever after through their nursing careers.

The latest cap count at Palo Alto-Stanford Hospital Center reveals that there are 228 different styles, representing graduates of that many schools of nursing, among the approximately 330 staff nurses.

According to a poll just made by Mrs. LaTella Atkisson, nursing service secretary, Palo Alto-Stanford Hospital nurses hail from 37 states and the District of Columbia, plus nine foreign countries: Canada, England, Scotland, Denmark, Netherlands, Norway, Ireland, Australia and the Philippines.

"Cap watching" is a favorite indoor sport among Hospital patients and personnel, to compare with bird watching outside. Styles range from perky pillboxes to starchy puffs, from mortarboards to cones, from flaring to tiny, austere to lacy. Variations may be quite hard to identify. Just a fold, a color of ribbon, a small initial, or an inch in size may be the key to identifying where the wearer is from.

Nurses caps have changed with the times, too. Typical is the development of Stanford's School of Nursing caps. The first uniform, worn from 1897 to 1902, included an organdy puff for a cap. The only trouble was, the cap wasn't washable! It had to be discarded and replaced by a new one periodically.

From 1903 to 1913, Stanford nurses tried a triangle, edged in lace, folded flat and worn like a hanky on top of the head.

World War I brought the present style, starched white cotton folded back. In 1929, a small red "S" was added to the left wing, to distinguish Stanford nurses from many others with similar styles. This cap is still worn, by student nurses as well as graduates. It is rather large, but has a built-in comb to keep it on.

-MORE-

Sometimes the position a cap is worn in is essential to identifying its school. For instance, some "mortarboard" styles must be worn flat on top, and some must perch on the back of the head. Their wearers must be expert with bobby pins or hat pins to hold the caps in the right position.

Almost all caps now are washable, but very few nurses do their own. They rely on the laundry to keep their caps in shape.

Foothill College and the Palo Alto-Stanford Hospital Center are taking steps to alleviate the critical shortage of inhalation therapists by setting up the first specialized program in the country to train students in the care of patients who have difficulty in breathing.

Through funds made available by the Manpower Development and Training Act, the College and Hospital Center will offer a 52-week training course beginning June 21. A certificate will be awarded upon completion of the course.

In September, a two-year program will begin. For this program, the College offers an Associate in Arts degree.

Dr. Nathan H. Boortz, director of technical education at Foothill College in Los Altos, has been working with Dr. Grant Fletcher, medical director, and Mervin Green, chief inhalation therapist of the Hospital Center, to set up the curriculum.

Although the general education, related science and therapy portions of the program will be taught at the College, the Palo Alto-Stanford Hospital and Sequoia Hospital in Redwood City will provide supervised clinical experience for the students.

Inhalation therapists are in great demand because respiratory equipment is not only becoming more complicated, but is being used in a greater variety of situations. There are only 1,900 trained inhalation therapists in the United States.

Respiratory equipment is used to restore breathing in patients after surgery and also is applied to many patients who suffer from such diseases as emphysema and asthma which cause breathing problems.

The initial class will be limited to 20 students and applicants are being screened now.

-MORE-

To qualify for acceptance in the course applicants must be 35 years old or under; must have a high school diploma; introductory courses in biology, chemistry, and algebra; qualifying scores on tests of college ability, and a personal interview.

Among the lecturers at the College will be Mr. Gilbert Davis, a well-known inhalation therapist from the University of Pittsburgh Health Center Hospitals.

At the Palo Alto-Stanford Hospital Center the students will be under the supervision of Dr. Grant Fletcher, Mervin Green, and Emile Cloutier, assistant chief inhalation therapist. At Sequoia Hospital the clinical instructor will be Mrs. Wilma Bright, chief inhalation therapist, under the direction of Dr. Robert Clark, chief of the anesthesia service.

Students will take both general and technical courses. Among the general courses required for the degree are effective writing and speaking, American government, and psychology. The scientific curriculum includes anatomy, physiology, physics, microbiology and health.

The clinical program will concentrate on inhalation therapy application and procedures on emergency, obstetric, pediatric, and surgical patients.

The election of Dr. Robert J. Glaser as a Fellow of the American Academy of Arts and Sciences has been announced in Boston. Dr. Glaser will become vice president for medical affairs and dean of the Stanford University School of Medicine July 1.

Currently, Dr. Glaser is president of the Affiliated Hospitals Center, Inc., in Boston and professor of social medicine at Harvard University.

Dr. Glaser was one of 140 leaders of scholarship, the professions, business and international affairs to be elected to membership in the Academy. Of the total, 120 Americans were elected to Fellowship while 20 distinguished persons from 14 other countries were elected to Foreign Honorary Membership.

The American Academy of Arts and Sciences, America's second oldest learned society, was founded in Boston in 1780 by John Adams and other revolutionary leaders of the Massachusetts Bay Colony. It was modeled after the learned societies of Europe, as the French Academy or the Royal Society of London.

Its other members from the Stanford University School of Medicine are Dr. Arthur Kornberg, professor and executive head of the department of biochemistry, Dr. Joshua Lederberg, professor and executive head of the department of genetics, and Dr. Karl H. Pribram, professor of psychiatry. In addition, 23 other faculty members of Stanford University are members of the Academy.

STANFORD MEDICAL CENTER NEWS BUREAU
Palo Alto, California

FOR FURTHER INFORMATION CONTACT: Joan R. McGee (DA 1-5310)

Like many women who give up a career to raise a family, Mrs. John W. Bellville wanted to work again. A registered nurse, she felt uncomfortable about seeking employment after being away from the profession for nine years.

Her husband, an associate professor of anesthesia at the Stanford University School of Medicine, told her about a refresher course offered at the Palo Alto-Stanford Hospital Center to bring inactive nurses up-to-date on the exploding advances in treatments and medicine. He was planning to lecture on pharmacology concepts in the course.

Being her husband's pupil didn't put a damper on the idea. Mrs. Bellville took the 149-hour refresher course and is now working part time at the Hospital and managing a family of four boys.

Mrs. Bellville is one of 185 nurses who have completed the refresher course which has been offered by the Hospital as a community service since 1961. About one-third to one-half of the nurses are employed by hospitals, agencies and private offices in the Bay Area. About one-fifth are employed here.

"I never felt alone in my endeavor," Mrs. Bellville said, "because most of the women have been away from nursing from 10 to 20 years and felt they needed current information on nursing practices."

The course is divided into two types of learning situations. In the mornings the nurses are assigned to work in units with selected patients under supervision of the Hospital's nursing staff. In the afternoons they attend classes.

"I gained a lot of confidence by working on a surgical unit where I learned to operate many types of new equipment," said Mrs. Bellville.

-MORE-

Part of their training is to keep a detailed record for patients cared for, including a brief history, the nursing problems presented, approaches and solutions to these problems and the nurses' conclusions.

Miss Marjorie L. Keys, assistant director of nursing service and director of inservice education, said the lectures and class discussions in the afternoons cover current procedures in nursing care, recent developments in medicine and new equipment.

Topics deal with the patient in the hospital, pharmacology, communicable disease concepts, rehabilitation, psychiatric concepts in nursing, medical-surgical nursing, the nurse's role in public health, and the legal aspects of nursing.

The Stanford University School of Nursing faculty, the Hospital nursing staff, doctors from the Medical School faculty, and members of the Palo Alto medical staff give of their time to teach the course.

The Hospital offers the course three times a year at convenient hours when children are in school. Each course has a limited enrollment of 12 qualified nurses who really want to work again.

Requirements for acceptance in the course are graduation from an accredited school of nursing, eligibility for current registration with the California State Board of Nurse Examiners, availability to commence and complete the course, and good health.

"There has been such a demand for the course that we have had to place some nurses on the waiting list," said Miss Keys.

Dr. Robert J. Glaser, who will become dean of the Stanford University School of Medicine and vice president for medical affairs in July, will make his first public appearance at Stanford University on Friday, May 21, at the annual Medical Alumni-Faculty Reunion.

Dr. Glaser will be introduced by Dr. Sidney Raffel, acting dean of the Stanford University School of Medicine at the reunion beginning at 10 a.m. in Dinkelspiel Auditorium. Other honored guests will be Dr. Walter C. Alvarez and Dr. Roy H. Morris, members of the class of 1905 of Cooper Medical College.

At the morning session the major speakers will be Dr. F. Eugene Yates, acting head and associate professor of the department of physiology, and Dr. David A. Rytand, Bloomfield professor of medicine.

Dr. Yates will discuss "A Minority Report on Adrenal Cortical Function," and Dr. Rytand "A History of the Circus Movement Hypothesis."

Noon recess will be free for informal, individual or class luncheon activities.

In the afternoon three separate clinical sessions, running concurrently, will be held at the Stanford University School of Medicine. Twenty faculty members will take part in the sessions beginning at 2 p.m.

Presiding at these sessions, which will cover a wide range of medical subjects, will be Dr. Halsted R. Holman, professor and executive head of the department of medicine; Dr. Norman Kretchmer, professor and executive head of the department of pediatrics, and Dr. Robert A. Chase, professor and executive head of the department of surgery.

In the evening there will be an alumni-faculty dinner dance for all alumni and faculty at the Villa Hotel in San Mateo. Special reunions will be held for classes of 1905, 1910, 1915, 1920, 1925, 1930, 1935, 1940, 1945, 1950, 1955A, 1955B and 1960.

Editors: Please add the following information to the release on the rededication program for the Palo Alto Hospital mailed May 10, 1965.

The Palo Alto city council voted Monday night to rename the Palo Alto Hospital the Herbert Hoover Pavilion.

The motion was made by councilman Robert Cooley who said, "Mr. Herbert Hoover was probably the most distinguished citizen of Palo Alto, a person of national and worldwide distinction. It seems most fitting that he should be honored in this way."

Herbert Hoover Pavilion will be dedicated at a public ceremony on Saturday, May 15 at 2:30 p.m. on the northeast lawn of the building, 350 El Camino Real, Palo Alto.

The Palo Alto Hospital, which has served thousands of Midpeninsulans for more than three decades, will be rededicated Saturday, May 15 at 2:30 p.m. during public ceremonies on the northeast lawn of the building.

The Hospital, located at 350 El Camino Real on the Stanford campus, will officially become a part of the Palo Alto-Stanford Hospital Center after a $1.3 million, 18-month renovation financed by the City.

After the ceremonies the public will be free to inspect the reconstructed areas and to view special exhibits on the first floor of the Hospital. Open house will also be held on Sunday from 2 to 6 p.m. On both days, staff members will conduct tours of the building.

Attending the ceremonies will be the Mayor and the Council of Palo Alto, civic leaders from the area, and others who were involved in establishing the Hospital in the 1930's and whose support has been important in making the renovation project possible.

Dr. Edward A. Barthold, Jr., chief of the Palo Alto medical staff, will introduce the Rev. Lynn P. Hunwick, president of the Palo Alto Ministerial Association, who will give the invocation. Mayor Bert Woodward, Jr. will make the presentation speech and Gordon P. Smith, president of the Palo Alto-Stanford Hospital Center board of directors, will then accept the renovated building from the City.

The four-story building provides accommodations for single and double rooms, wards, and a separate intensive care unit. There are 50 private rooms of the total 152 beds. In addition, there are five observation rooms and three solaria. The Hospital provides the following services: X-ray, electrocardiography, hematology and urinalysis laboratory, a blood banking area, and physical and occupational therapy. The Palo Alto-Stanford Hospital Center Auxiliary will run a gift shop.

- MORE -

One of the many remodeled areas is the reception lobby which has been furnished in Danish modern furniture of orange and yellow upholstery. The walls, floors and ceilings in the corridors have been refinished and painted to give the appearance of a new building.

In patient rooms colonial beds from the 1930's rest underneath TV sets from 1965 in a contrast of eras. Modern light fixtures and new call signals for nurses have been installed in each room. The old, dark brown doors for each patient room have been refinished in a light birch shade.

Intensive care will be provided in a separate unit for 10 patients. The unit has three double cubicles for patient beds. Two private isolation rooms and one double occupancy isolation room with glass partitions face the nurses' station so any change in patients' condition can be seen instantly.

Some of the newest models of medical and hospital equipment worth $300,000 have been installed to give patients the best possible care.

In the dietary department three radar ranges bring food to the desired temperature for serving. Since the ranges heat foods so rapidly, they can be used as the trays are being assembled along the movable food tray line. Assembled trays are immediately put into movable food carts and brought to the patients.

The X-ray department is equipped with the latest overhead tube hangers which are mobile so film can be taken of different parts of the body. X-rays can be turned out in just six minutes by a new processing machine.

In the department of cardiology two EKG machines are set up. A dataphone is being set up on a trial basis which will make possible transmission of electrocardiograph impulses by telephone line from the Palo Alto Hospital to the cardiology laboratory at the Center where the tracing can be graphed, interpreted and filed.

-MORE-

The Palo Alto Hospital was built and equipped in 1931 at a cost of about $500,000, more than half the cost of the present renovation. A $250,000 bond issue approved by Palo Alto citizens covered only about half the cost of erecting the 100-bed structure. The remaining money came from private contributions. In the campaign for funds, the Women's Auxiliary of the Palo Alto Hospital played an important role.

The Hospital was designed by Reed and Corlette, architects of Oakland, and built by the K. E. Parker Company of San Francisco. It was managed by Stanford University which also had furnished the site on lease to the City.

In 1939 a four-story wing was added to meet the needs of a growing community. At that time the 170-bed hospital was the largest on the Peninsula south of San Francisco.

It did not take long before the community began to outgrow it again. And after the war, plans were undertaken to construct the Palo Alto-Stanford Hospital Center three quarters of a mile near the foothills.

With the opening of the new Center in 1959, the City councilmen and Stanford officials agreed to discontinue use of the Hospital, at least temporarily.

It soon became apparent, however, that the 437 beds in the Center was insufficient to take care of the increasing patient population and steps were taken to remodel the Palo Alto Hospital.

Acting on the request of the Hospital Board, the Palo Alto City Council in 1962 approved funds for extensive renovation of the building.

The architectural firm of Stone, Marraccini and Patterson of San Francisco designed the project. Work was done by the Beacon Construction Company of San Francisco.

"I want to help victims of accidents and crippling diseases return to an active life," said Walter Hapke, a student in physical therapy at Stanford Medical Center.

Hapke and 40 other students are out to prove that statement. One-half expect to graduate in September and start a full-time career in physical therapy.

Thinking back over the past months, however, these students could well be overwhelmed by the scope of the program. They must give patients moral support during trying times. They must master exercises for every muscle of the body. And the courses they take are tough. But through it all optimism runs high.

These students know that hospitals, crippled children schools, rehabilitation centers need them when they graduate. There is only one physical therapist for every 28,000 people. Stanford is one of 43 colleges and universities in the country with a physical therapy program. It is one of five in California.

The students also know they will be well prepared for a profession because they are now getting first-hand experience with patients who have a wide variety of illnesses and physical disabilities. Predominantly, patients include those with fractures, arthritis, cerebral vascular accidents, cerebral palsy and other conditions. Persons injured in industry, sports and traffic also require treatment.

Last fall the students started practicing therapeutic exercise on each other in a laboratory. This is part of the program to help them gain proficiency in the numerous techniques used to assist patients in restoring motor functions.

In the laboratory the students also learn to operate special equipment such as diathermy and microwave for heat treatments and the electrical stimulator for passive exercise. A therapeutic pool is available for certain exercises.

-MORE-

When a student becomes proficient in a procedure, he treats the patient under close supervision of a physical therapist in the Palo Alto-Stanford Hospital. Relating the theory from the text books and laboratory to an actual patient situation is the most important part of their training.

One student said, "I have seen patients overly anxious to recover. One, for instance, wanted to regain function of a right arm practically overnight. I watched the patient straighten out her fingers which before treatment had been held tightly in a fist. I tried to encourage her to be happy with this little improvement."

"Walking with the aid of a brace is much better than not walking at all," said another student.

"We teach the students to understand the psychological needs of the patients, as well as to cope with the physical problems," said Miss Lucille Daniels, director of the division of physical therapy of the Stanford University School of Medicine.

After the students finish the classes and part-time clinical experience, they are assigned full time to affiliated hospitals and treatment centers during the summer. After this experience they are eligible for a degree or a certificate.

The division offers curriculum leading to the B.A. degree for undergraduates or a certificate for persons who have a bachelor's degree but no major in physical therapy. The M.A. degree is also offered to students interested in administration, teaching and research. Those working in the field often return to school to bring themselves up-to-date.

Ninety percent of the students this year at Stanford are working toward a certificate or Master's degree, according to Miss Daniels.

To qualify for practice the students study anatomy, physiology, chemistry, psychology, clinic procedures, kinesiology and many other subjects.

"It's a demanding course," admits Miss Daniels. "But it is worth the effort when they enter a profession feeling confident that they have the background to help a patient recover."

Eighteen single-bed rooms have been made available in the Palo Alto-Stanford Hospital to meet the requests from patients.

These rooms were temporarily converted into semi-private rooms last year to meet the growing demand for more beds. But the opening of additional accommodations in the Palo Alto Hospital helped ease the shortage, according to Mrs. Carol Profant, management analyst.

The Palo Alto-Stanford Hospital Center has a total of 60 single-bed rooms--39 in the Palo Alto-Stanford Hospital and 21 in the Palo Alto Hospital. There will be 50 private rooms in the Palo Alto Hospital when the renovation is completed this month.

The Palo Alto Hospital will be dedicated May 15.

GONE ARE THE DAYS

Gone are the days when nurses had to shake down and clean patient temperature thermometers as Mrs. Irene T. Springer, nursing aide at the Palo Alto-Stanford Hospital Center is doing in the picture at the left. And gone are the days when nurses placed 12 thermometers at one time in an electric thermometer shaker as Miss Evelyn Bruyn, nursing aide, is doing in the center picture.

Replacing the old-fashioned methods is a centrifuge which shakes down 112 thermometers in one minute, a saving of about 100 minutes each day over the former method.

The Hospital's central service now dispenses disinfected, ready to use thermometers to each nursing station. After one use, nurses place the thermometers in receptacles and return them to central service for cleaning, disinfecting and packaging. Central service processes and shakes down about 1200 thermometers each day.

In the picture at the right Mrs. Annie Mitchell, central service aide, gathers clean thermometers to place in the centrifuge.

Attention Editors: This may be of interest to travel editors.

FOR FURTHER INFORMATION CONTACT: Joan R. McGee (DA 1-5310)

Dr. Joseph P. Kriss, professor of radiology at the Stanford University School of Medicine, and his family know exactly how to relax on a summer vacation.

He, his wife, Reggie, and their two boys, Eric, 16, and Mark, 12, are loading their four bicycles on an airplane and flying off on June 20 for a six-week cycling vacation through the countryside of France.

By deliberately biking off the beaten path, the Krisses of 735 Mayfield Dr., Stanford, hope to meet the French people, see the chateaux and cathedrals and learn about the specialties of the various quaint villages.

They are confident that their French bikes with 10 gears, which they used on vacations through Hawaii and New England, are sturdy enough to make the 1,000-mile trip.

To take care of any mishaps along the way, Dr. Kriss will carry a tool kit in a satchel on the back of his bike which is equipped with numerous handy gadgets. He learned from experience that it is not always possible to find a mechanic who can handle the technical problems of their racing bikes with alpine gears.

Before packing the Krisses considered the weight of tools, clothes, passports, travelers checks and Michelin maps. Since travelling light is essential for bike riding, each family member must limit himself to 10 pounds.

Each selected their limited wardrobe with a great deal of ingenuity. Mrs. Kriss is taking two short shifts with slits in the sides to wear while riding so her legs will become evenly tanned. The men are taking two pairs of bermuda shorts. A change of underwear, bathing suits and light-weight madras jackets complete their riding outfits.

They are also prepared to change into their only dress outfit after they have stopped for the night. Few people would be able to recognize the dusty bicyclers then.

The Krisses have not set up any overnight reservations, but are planning to stay in various places, such as hostels, inns and French homes.

"We like the sense of adventure of not knowing where we'll be next," Dr. Kriss said. "And in biking, each road or town has a special meaning as you slowly pedal along."

Many friends are wondering how they will manage to resist the French wine. The Krisses think it will be a temptation, but realize that wine drinking and bike riding don't mix during the day.

A new technique for measuring radiation dosage will be the subject of an International Conference on Luminescence Dosimetry at Stanford University June 21-23.

The method of measurement depends upon the fact that certain materials which have been exposed to ionizing radiation such as X-rays will subsequently give off visible light when they are heated or placed under ultraviolet light. The amount of light given off is directly related to the amount of radiation exposure.

Luminescent dosimeters cover a much wider range of exposure than electronic devices made so far. In addition, they are far more compact. A small capsule of material can take the place of a relatively large, easily damaged piece of equipment.

Dosimeters using luminescent materials have been devised for people who might be exposed to radiation in their occupations. Capsules are also being implanted in patients to measure dosage given in the course of radiation therapy, or in animals for experiments.

Identical capsules can be exposed at different locations and then processed at one facility. This provides standard readings so that the exact output of one X-ray machine or similar device may be very precisely compared with that anywhere else in the world. This is particularly important for investigators who wish to compare their results with those of other laboratories.

The conference at Stanford will attract 250 persons. Approximately 40 scientific reports will be presented by investigators from the United States, eight European nations, Japan, and India.

The meeting is being sponsored by the Stanford University School of Medicine's Department of Radiology, the U.S. Office of Naval Research, and the U.S. Atomic Energy Commission.

FOR FURTHER INFORMATION CONTACT: Joan R. McGee (DA 1-5310)

A 61-year-old bachelor who is deaf reported that he "heard" sounds in experiments in which two researchers from the Stanford University School of Medicine electrically stimulated his hearing nerve.

Anthony Vierra of San Jose, Calif. was a patient at the Veterans Administration Hospital in Palo Alto before he volunteered for the experiments last year.

In May 1964 Dr. F. Blair Simmons, assistant professor of surgery, and Dr. John M. Epley, a resident in otolaryngology, implanted six tiny wires into the man's auditory nerve. The auditory nerve is located in the inner ear, one of the three sections of the ear.

Normally, sounds come into the inner ear and, in a way not completely understood, trigger the nerve fibers of the auditory nerve. These fibers produce the electrochemical pulses that travel along the auditory nerve to the brain which interprets them as sounds.

In this experiment the two researchers stimulated the auditory nerve fibers directly by applying very small pulses of electrical current to an electrode or pairs of electrodes.

The electrodes led to a connector behind the right ear, where external contact could be made.

By stimulating the nerve fibers, the researchers produced a variety of sensations, covering a range of pitches between very low sounds like hums to very high sounds like violins.

"Although the range and variety was insufficient to reproduce speech for Vierra, he could tell speech from other sounds," Dr. Simmons said, "probably because of the difference and changes in rhythm or amplitude."

-MORE-

The researchers said that it was possible to play simple tunes such as "Jingle Bells" and "Mary Had a Little Lamb." Vierra was able to identify these tunes from what he remembered before he became deaf.

This is the first time that such extensive and discrete electrical stimulations of the auditory nerve have been carried out in man.

Dr. Simmons explained that the purpose of the study was to gain further knowledge about hearing and about the possibilities of implanting artificial hearing devices in deaf people. The results suggest that speech communication via direct nerve stimulation might be possible in the future. However, it would require more research and certainly more than six wires in the nerve.

"We were justified in conducting this clinical trial because our laboratory has had extensive experience in permanently placing electrodes within the ears of experimental animals for many years. Electrical stimulation of the brain has been shown technically feasible," Dr. Simmons said.

The study was reported in a recent issue of SCIENCE, weekly magazine of the American Association for the Advancement of Science. It was carried out in cooperation with other scientists at the Bell Telephone Laboratories in Murray Hill, New Jersey.

The cause of Vierra's deafness is not known, but researchers think it was probably associated with a condition called retinitis pigmentosa which is an inflammation of the eye. Vierra has apparently had the condition "in some degree" since childhood.

Because Vierra is partially blind, probably due to that condition, he is able to see written messages only in large block letters. And this is how the researchers communicated to him. The condition, however, has not affected his speech.

Vierra lives at home now. Transportation to and from the Stanford Medical Center is provided by the Veterans Administration Hospital in Palo Alto.

Dr. Simmons and Dr. Epley intend to continue to refine the techniques with the eventual long-term goal of learning about which types of "electrical sounds" can be eventually "understood" by a previously deaf person.

######

(Mailed June 14, 1965)

ANTHONY VIERRA, a 61-year-old deaf man, "heard" two out of several tunes being used during an experiment in which Dr. F. Blair Simmons, assistant professor of surgery, and Dr. John M. Epley, a resident in otolaryngology of the Stanford University School of Medicine, stimulated his hearing nerve via electrodes connected behind his right ear. Because Vierra is partially blind, he can read messages only in large block letters.

FOR RELEASE AFTER 11 A.M., SATURDAY, JUNE 12

Editors: Names of students receiving M.D. degrees in your area will be included in a story mailed from Stanford University on June 11. Home addresses of award winners are listed on page 2.

Stanford University School of Medicine will award 46 degrees June 13 to students in the second class to complete the new five-year curriculum inaugurated when the school moved from San Francisco to the Stanford campus.

Six outstanding students received awards at the convocation of the class of 1965 held at the Medical Center on Saturday, June 12.

John D. Johnson and Harvey Leon Ozer received the Borden Undergraduate Research Award of $250, given to each of them by The Borden Company Foundation, Inc. for "research during their undergraduate career deemed most meritorious."

The L. A. and Marian S. Hopkins Award of $100 went to senior student H. Wayne Tobin for outstanding work in dermatology.

Winners of the Harold K. Faber Pediatric Award of $200 were John D. Johnson and Bruce Malcolm Tune. This award is given to potential contributors to child health in recognition of accomplishments in pediatrics.

Daniel Page Stites won the Robert T. Legge Award, given by the Northern California Chapter of the American Industrial Hygiene Association to a senior student who shows the most aptitude and interest in the study of preventive occupational health. The award is $20 for a book of his choice.

Timothy Beveridge Coburn, a second-year student, was given the Roche Award of an engraved gold wrist watch as an "outstanding student of medicine who has successfully completed the first two years of medical school."

-MORE-

Dr. Sidney Raffel, acting dean of the Stanford University School of Medicine, welcomed the guests and presented the awards. Dr. Harold K. Faber, emeritus professor of pediatrics, presented the award named after him, the Harold K. Faber Pediatric Award. Dr. Halsted R. Holman, professor and executive head of the department of medicine, delivered the address, and Dr. C. Howard Hatcher, professor of surgery, administered the Hippocratic oath.

Students and their parents' names and addresses are listed below:

LOS ANGELES, CALIF.----------Bruce Malcolm Tune
Mr. & Mrs. Buford Tune, 2858 Motor Ave.

CRAWFORDSVILLE, IND.----------John D. Johnson
Dr. & Mrs. Willis H. Johnson, 1003 South Grant

DORCHESTER, MASS.----------Harvey Leon Ozer
Mr. & Mrs. Samuel L. Ozer, 11 Ashton St.

MARGATE, N. J.----------Daniel Page Stites
Mrs. Helen Stites, 13 North Exeter Ave.

BEDFORD VILLAGE, N. Y.--------Timothy Beveridge Coburn
Dr. & Mrs. Alvin S. Coburn, Rt. 22

BROOKLYN, N. Y.----------H. Wayne Tobin
Mr. & Mrs. George T. Tobin, 298 East 45th St.

FOR RELEASE FRIDAY, JUNE 11, 1965

A spontaneous mutation resulting in mice born without sebaceous glands, or oil glands, was reported today for the first time by two investigators from the Stanford University School of Medicine.

The new finding will enable researchers to study the normal function of the mysterious oil glands and their role in diseases of the skin.

The sebaceous glands are millions of tiny oil factories scattered over the body. Until now all that was known about their function was that they lubricate the hairs and skin, keeping them in a constant well-oiled state.

The discovery was reported by Dr. Allen H. Gates, assistant professor of obstetrics and gynecology, and Dr. Marvin Karasek, assistant professor of biochemistry and dermatology, in SCIENCE, weekly magazine of the American Association for the Advancement of Science.

According to their report, studies of the oil glands have been generally hampered by the lack of animals with this kind of skin abnormality. Spontaneous mutations, or variations in appearance of animal offspring due to a change in a gene, are rare in a laboratory. And artificially induced mutations in animals are frequently lethal.

Following their discovery, Dr. Gates and Dr. Karasek exchanged skin grafts between normal and mutant mice to determine the effects of the mutation and whether or not it was limited to the skin of the laboratory animals.

-MORE-

They found that the skin of the mutant mouse lost some of its scales and appeared normal when grown on the normal mouse. When normal skin was transplanted onto mutant host animals, it stimulated hair growth and normal skin development in regions adjacent to the normal skin.

These results, the researchers said, suggested that the mutation resulted in the loss of some chemical substance necessary for the normal growth of hair and skin, and that this substance was being supplied by the normal skin tissue.

In further studies to find the missing chemical, Dr. Karasek, and an associate, Dr. David I. Wilkinson, looked into the composition of fats in the skin of normal and mutant mice by the sensitive technique of gas chromatography. This technique permits researchers to analyze simultaneously different compounds present in one substance.

They observed that certain fatty acids present in the normal mice were lacking in the mutant animals.

The Stanford investigators plan to study further and identify this missing substance to determine if it plays a role in the development of the skin condition in these mice. By these observations they hope to understand better diseases of the oil glands such as acne which causes untold misery for many young people and for a smaller number of adults.

#######

(Mailed June 8, 1965)

#1

#2

#1 Dr. Marvin Karasek, assistant professor of biochemistry and dermatology at Stanford Medical School, displays mice that may help in studies of diseases of the skin. Mouse with darker skin, discovered by Dr. Allen H. Gates, also of Stanford, has no oil glands. The discovery will give researchers an opportunity to study the role of the mysterous oil glands.

#2 Normal mouse at left is contrasted to mouse without sebaceous glands or oil glands. The skin abnormality, a result of spontaneous mutation, was reported by Drs. Allen H. Gates and Marvin Karasek of Stanford University School of Medicine in a recent issue of SCIENCE.

Editors: This story was transmitted on Business Wire June 2, 1965

Dr. Lyman M. Stowe, former associate dean of Stanford University School of Medicine and one of the chief planners of its new 5-year curriculum, died early today of a heart attack. He was 51.

Since 1963 Dr. Stowe had served as the first dean of the University of Connecticut Medical School. He was stricken at his home in Farmington, Conn., and died two hours later.

"We on the faculty are all saddened by Lyman's death," Acting Dean Sidney Raffel of the Stanford medical school said. "He made a very large contribution to the school that exists today. We also were proud that he was building such a fine school in Connecticut."

Dr. Stowe joined the Stanford faculty in 1949 as assistant professor of obstetrics and gynecology. In 1955 he became associate professor and assistant dean. Three years later he was appointed associate dean. He received both his A.B. and M.D. degrees from Yale University.

In addition to serving as one of the principal architects for the Stanford curriculum, he also played a key role in planning the physical facilities for the medical school in the new Stanford Medical Center at Palo Alto.

Dr. Stowe is survived by his widow, Lois, and three sons, Maynard, 17, David, 14, and John, 13. There will be no funeral services.

Associate director David B. Starkweather has resigned to pursue a career in teaching hospital and medical care administration, Dr. LeRoy E. Bates, director of the Palo Alto-Stanford Hospital Center, announced today.

Starkweather advised Dr. Bates of his desire to begin work this fall for his doctorate degree in medical care organization at the School of Public Health of the University of California at Los Angeles.

Expressing his personal regret at Starkweather's decision, Dr. Bates noted that "Mr. Starkweather has done an outstanding job as associate director and has provided new ideas and leadership to the staff during the Hospital Center's formative years. We know that all persons directly and indirectly associated with the Center share our best wishes to Mr. Starkweather for even greater success in the future."

Starkweather joined the Hospital staff in 1958. He served consecutively as assistant and associate administrator, and was acting administrator from January to July 1964. He holds a master's degree in Hospital Administration from Columbia University's School of Public Health.

FOR RELEASE MONDAY, JULY 19, 1965

A promising new treatment of the commonest killer of newborn babies was reported today by physicians from Stanford University School of Medicine.

The killer, called hyaline membrane disease or respiratory distress syndrome, affects 25,000 newborn babies in the United States.

The treatment consists of applying prolonged artificial respiration to these babies using a plastic breathing tube inserted into the windpipe through a nostril. Breathing is facilitated by a respirator which blows air or oxygen down the windpipe into the lungs.

Of 19 babies treated with artificial respiration, 12 survived. Length of treatment ranged from several hours to 28 days, the physicians said. Their report was published in the Journal of the American Medical Association.

The physicians are Dr. D. Vernon Thomas, associate professor of anesthesia, Dr. Grant Fletcher, assistant professor of anesthesia, Dr. Philip Sunshine, instructor in pediatrics, Dr. Irwin Shafer and Dr. Marshall H. Klaus, assistant professors of pediatrics.

"It must be realized that these babies getting respirator treatment are probably the 50 percent who would ordinarily die," Dr. Thomas said. "We treat the less severe cases with the usual methods and only when these simpler approaches are failing we resort to artificial respiration."

Although anesthesiologists use artificial respiration to save adult patients with breathing illnesses such as polio, tetanus and severe lung disease, the treatment has rarely been applied to babies suffering from the respiratory distress syndrome.

The reason is that in adult patients the plastic breathing tube usually must be inserted into the windpipe through a temporary surgical opening in front of the neck. When the illness is over the tube is removed and the opening heals over.

-MORE-

But in small babies there can be serious difficulty in removing the breathing tube.

"Often, even though the lungs have healed, a swelling develops inside the windpipe at the surgical opening and when the tube is removed the baby's breathing becomes obstructed," Dr. Thomas explained.

At first Dr. Thomas and his associates tested the application of prolonged artificial respiration to babies with a breathing tube inserted through the mouth, but the tube tended to slip out. The problem was solved by passing the tube into the windpipe through a nostril.

"Blood tests have shown that the respirator is consistently able to increase the abnormally low oxygen level and to reduce the excessively high carbon dioxide levels toward normal. Both these changes help open the blood vessels of the lungs and hasten healing," Dr. Thomas said.

According to a recent theory developed by Stanford and University of California pediatricians, hyaline membrane disease is caused by a failure of the protective reflex which shifts the newborn over to the task of breathing for himself.

At birth the pulmonary blood vessels dilate immediately, and a full supply of blood begins pumping into the lungs. But, if for any reason the blood of the fetus becomes low in oxygen, the protective reflex comes into play and cuts down on the supply of blood to the lungs and kidneys and increases the flow to the heart and brain.

Prolonged artificial respiration has been one way of counteracting this, Dr. Thomas said.

#######

(Mailed July 15, 1965)

Dr. Vermon Thomas, associate professor of anesthesia at Stanford University School of Medicine, has just finished placing a plastic breathing tube in a baby's windpipe to make sure air from a respirator will reach the infant's lungs. Dr. Thomas recently reported that prolonged artificial respiration showed promising results in the treatment of newborn babies suffering from the respiratory distress syndrome or hyaline membrane disease.

Thirty-five students, six years younger than the usual Stanford medical students, set out on a treasure hunt in the Stanford Medical Center which was unlike any other -- to find bacteria.

Dressed in doctors' white coats they roamed through the cafeteria, kitchen, animal facilities, wash rooms, elevators and other places to collect bacteria samples in laboratory petri dishes.

Medical Center employees assisted them in their search.

"I thought they were medical students who were doing a study," gasped a head nurse.

Another employee said, "I thought they were staff members of the infectious disease laboratory."

After collecting bacteria samples, normally found in any environment, the students went back to the Fleischmann Laboratories of Stanford University School of Medicine to study them.

These students, at the end of their freshmen and sophomore years at Ravenswood High School, are performing the bacterial studies as part of a summer science program going on at the medical school from June 21 to July 30.

The program aims to expose them to the frontiers of biological science and medicine in a setting which gives them the opportunity to rub elbows with the people who make the Center tick.

The students are an interracial group selected from over 200 applicants on the basis of grades in science, math and English; science teachers' recommendations, and scores on tests of verbal and scientific ability.

- MORE -

Dr. Leonard A. Herzenberg, associate professor of genetics, is director of the program of lectures, discussions, laboratory work and field trips which is supported by a grant from the National Science Foundation.

He and about 30 members of the faculty and staff of the departments of biochemistry, genetics, medical microbiology, medicine, pediatrics, pharmacology, psychiatry, surgery and others helped organize the program and are giving their time to teach various sections of the course.

Also assisting in the program are three Stanford medical students, Fred Burbank, Ann Klompus and Mark Sapir, and a Ravenswood High School science teacher, Harvey Cole.

To make discoveries about genetics, cell biology, biological macromolecules or mammalian biology each student must do research on his own. Therefore, a major part of their activities are devoted to experiments, operating the latest equipment and searching for answers in available books.

But students are also discovering, as one student put it, that "it is very good to know that doctors have a sense of humor like we do."

Participating faculty members have found that the students are diving into the medical subjects with an astonishing intellectual interest. They ask questions which faculty members must answer bluntly that, "we just do not know. This is something your generation will have to answer."

To be effective teachers, the faculty must find out what motivates high school students and what they like. Dr. Herzenberg commented, "it is rewarding when students of varied educational backgrounds respond."

"Even more rewarding," he added, "is that some will continue to work in the Medical Center after the course ends."

"You look handsome," said the nurse as she saw Antonio Victorio for the first time after the boy's cleft lip and palate was corrected through a delicate operation.

The bright-eyed, 13-year-old teenager from Mexico was born with a gaping hole in his upper lip.

When Stanford University surgeons today removed the stitches from his mouth, Antonio's future suddenly looked bright.

It was not so several months ago. Antonio was being reared by his grandmother in the small village of La Azteca near San Luis Rio Colorado, Sonora. His parents live with six other children in a one-room house.

All his life Antonio's friends teased him mercilessly and he had dropped out of school.

Then Father James Poggi of St. Joseph Seminary in Mountain View, Calif., a volunteer with the Catholic Church's Latin American Mission Program, met Antonio.

He became interested in the boy's plight, and promised to see if he could help him when he got back in the San Francisco Bay Area.

Through friends, Dr. and Mrs. Edward Lynch of Mountain View, Father Poggi was introduced to Dr. Donald J. Prolo, a resident in surgery at Palo Alto-Stanford Hospital Center. Dr. Prolo in turn contacted Dr. Robert Chase, executive head of the department of surgery at Stanford University School of Medicine.

-MORE-

The Lynches assumed responsibility for Antonio and the boy was brought by Mr. and Mrs. Larry Rangle of Menlo Park who offered to drive him from Mexicali to the Peninsula.

The first operation to close the boy's lip was performed in February. The second operation to correct Antonio's cleft palate was done last week. Both operations were successful.

Dr. Chase said the surgery is rarely performed in this country on a child of Antonio's age. A cleft of the lip and palate usually is corrected in children by surgery between the ages of 6 months and 2 years.

Shy at first, Antonio now is a close friend of the Lynch children and the six children of Mr. and Mrs. Barney Cervantes of Mountain View, where he is staying.

Antonio is learning to speak a bit of English. Father Poggi describes him as friendly and very well-mannered. "He also is very generous," Father Poggi said. "He had some candy the other day and gave it all away to the other children."

A new method of relieving rigidity of taut muscles--a major obstacle to rehabilitation for some patients with strokes, cerebral palsy, and multiple sclerosis--was reported today by three investigators from Stanford University School of Medicine.

The new technique involves the treatment of taut muscles through injection of phenol, a common drug, into nerves and nerve roots.

The physicians are Dr. Daniel Feldman, associate professor of medicine in rehabilitation, Dr. Jordan Katz, assistant professor of anesthesia, and Dr. Leslie Knott, assistant professor of medicine in rehabilitation. They described recent preliminary clinical trials in the September 20 issue of the Journal of the American Medical Association.

One study involved 22 patients. Cause of muscle rigidity in those patients included strokes, spinal cord injuries, multiple sclerosis, cerebral palsy, brain injuries, and brain tumors.

Using a small dose of phenol in saline solution of water in quantities varying with nerve size, the Stanford researchers injected 56 nerves. The degree of rigidity, motion and other clinical criteria were evaluated by the investigators before and after treatment. Physical therapists recorded changes in the patients' responses to rehabilitation treatment.

Immediate relief of rigidity of 50 percent or more occurred in 31 of 56 nerve injections. "In seven of these, rigidity was practically eliminated and considerable increase in the range of joint motion was noted," the physicians said.

-MORE-

The three investigators agreed, however, that lack of uniform action and relatively short periods of relief of rigidity were major problems with phenol therapy. Relief lasted from three days to more than a year. In 22 of the 31 nerve injections, duration was three to four weeks. There were no apparent adverse effects.

"Despite short-term action, this method is particularly valuable in a number of patients because phenol appears to have a temporary effect on taut muscles, thus permitting evaluation of the possibility of physical therapy or surgery or both," the physicians pointed out.

The investigators described one cerebral palsy patient who was treated with this method. After nine weeks of marked, continuous relief of rigidity in finger and wrist muscles, the patient underwent surgery--transplantation of the wrist flexors to the wrist extensors. A year later the patient had greatly improved strength in wrist extension. Also there had been no evidence of recurrent rigidity in extensor or flexor muscles of the wrists and fingers.

The investigators stressed that more laboratory work is needed before more prolonged and consistent results with phenol injections can be obtained.

"After two years of experience our results indicate it is a benign technique helpful to a number of patients," they said. "Although it is hoped that a drug may be developed to eliminate rigidity entirely, this technique seems to be a potential rehabilitative method avoiding further nerve function destruction, and should be tried in those patients who do not respond to usual therapy."

The only postdoctoral program in the West for training veterinarians in laboratory animal medicine has been established at the Stanford University School of Medicine.

The program is one of seven in the country set up by a grant from the National Institutes of Health to help alleviate the shortage of veterinarians needed to direct animal research facilities and care for experimental animals.

"Professional care of laboratory animals is necessary to provide researchers with normal and healthy animals needed for medical research projects," said Dr. Orland A. Soave, assistant professor of preventive medicine and director of the animal care facility.

Under Dr. Soave's supervision veterinarians will receive three years of training in the care, diseases and use of laboratory animals in scientific research. They will also have the opportunity to earn an M.S. degree in a specialty of their choice.

The medical school's facility offers trainees nearly 50,000 animals for study and observation, a clinical and diagnostic laboratory and a research program in problems of animal care.

Requirements for appointment to the first year of the training program are graduation from an accredited school of veterinary medicine with a doctor's degree in veterinary medicine and qualification for admission to the Stanford University Graduate School.

A select group of 64 students with outstanding scholastic records have enrolled in the Stanford University School of Medicine to prepare themselves for careers in medicine.

The class of 1970 is composed of 58 men and six women who were chosen from over 700 applicants on the basis of aptitude and past records.

They come from 22 states and from Hong Kong. Twenty-five of the 64 are residents of California.

The new class represents 35 different undergraduate institutions in 14 states. Twelve of the students attended Stanford University.

EDITORS: Student names, and parents' names and addresses follow:

CALIF., ARCADIA - Virginia Frances Simson, Mr. and Mrs. Jerome Simson, 1020 So. First Ave.
BERKELEY - William Robert Roeske, Mr. and Mrs. William F. Roeske, 2221 Parker, Apt. 1.

Prof. Theodosius Dobzhansky of the Rockefeller Institute, a noted authority in the fields of genetics and evolution, will give the 34th course of Lane Medical Lectures at Stanford University School of Medicine.

He will speak on "The Genetic Load" October 11, 13, and 15 at 4:30 p.m. in Room M106. The lectures will also be shown on closed-circuit television in Rooms M104, M112 and M114.

Professor Dobzhansky is the author of two books, GENETICS AND THE ORIGIN OF SPECIES and MANKIND EVOLVING. The latter book was based on the Silliman Lectures which he delivered at Yale University in 1959, in honor of the Centennial of Charles Darwin's ON THE ORIGIN OF SPECIES.

In MANKIND EVOLVING, Professor Dobzhansky expressed the view that "evolution need no longer be a destiny imposed from without; it may conceivably be controlled by man, in accordance with his wisdom and values."

Professor Dobzhansky was born in Russia and came to the United States in 1927, after having served as a lecturer in genetics at the University of Leningrad. From 1927 to 1929 he was a fellow, with Professor T. H. Morgan, of the International Education Board of the Rockefeller Foundation. From 1929 to 1940 he served consecutively as assistant professor and professor of genetics at the California Institute of Technology. In 1940 he was appointed DaCosta professor of zoology at Columbia University.

He currently serves as adjunct professor of zoology at Columbia in addition to his responsibilities at the Rockefeller Institute.

-MORE-

Professor Dobzhansky's scientific career is replete with honors. This year, on the other side of the Atlantic, he received the degree of Doctor Scientiarum Agronomicarum, Honoris Causa, from the University of Louvain, and in this country he was among 11 recipients of the National Medal of Science, awarded by President Johnson at the White House.

His professional affiliations are numerous. He has long been a member of the Genetics Society of America of which he is a past president. He has also been president of the American Society of Naturalists, the Society for the Study of Evolution, and the American Society of Zoologists. He is a member of the National Academy of Sciences, Royal Swedish Academy of Sciences, Royal Danish Academy of Sciences, and other distinguished societies in Brazil, Germany, and Italy.

The Lane Medical Lectures, founded in 1896 by Dr. Levi Cooper Lane, are given biennially on medical subjects. The lectures are open to the medical profession, students, teachers, and research workers in medicine and allied sciences.

Dr. Dobzhansky will also speak on "Man and Evolution" at the Tuesday Evening Series October 12 at 7:45 p.m. in Dinkelspiel Auditorium. The Series are sponsored by the committee on public exercises at Stanford University.

FOR IMMEDIATE RELEASE

STANFORD - Stanford University students will open their "Stanford Jazz Year" with a concert by Louis Armstrong and his All-Stars in Frost Amphitheater at 2 p.m. Sunday, Oct. 10.

The famed "Satchmo," who needs little introduction to jazz fans or the general public, spans a career of 50 years in the entertainment world akin to the history of jazz itself.

Tickets for the Armstrong concert and a subsequent concert Oct. 31, featuring Ella Fitzgerald with Duke Ellington and his orchestra, may be obtained at the Tresidder Union box office at Stanford or by mail to P.O. Box 6508, Stanford.

Rick Bale, a senior psychology major from Tiburon, heads a committee of a dozen students who have been planning the nine-month jazz festival since last spring.

They have programmed a series of films, exhibits and lectures to parallel the concerts, which will be held in winter in the 1700-seat Memorial Auditorium and in the open-air amphitheater during the fall and spring.

Ralph J. Gleason, jazz editor of the San Francisco Chronicle and syndicated critic, opens the fall lecture series Oct. 4 with a discussion of "Jazz and American Society."

This and all other lectures of the series will be offered at 4:15 p.m. in Tresidder Union on successive Mondays. Admission is free, but limited seating allows admission only to students and members of the Stanford community.

The Oct. 11 talk will feature Marshall Stearns on "Origins and Definitions." Dr. Stearns is professor of English at Hunter College, New York, and the author of a classic work, "The Story of Jazz."

Philip F. Elwood, jazz critic of the San Francisco Examiner, jazz director of Station KPFA, and instructor at the Peralta Colleges in Alameda County, will speak Oct. 18 on "Jazz in the '20's: The Old Order Changes."

Veteran jazz promoter and impresario John Hays Hammond, executive producer at Columbia Records, will close the October lecture series on the 25th with a talk on "The Swing Era."

Negotiations are under way for several other well-known jazz artists to appear on campus.

Also scheduled during the year are lectures by Ira Gitler, former editor of "Downbeat"; John Lewis, leader of the Modern Jazz Quartet; Singer Jon Hendricks of the former Lambert-Hendricks-Ross trio; and Critics Leonard Feather and Nat Hentoff.

The display gallery on the second floor of Tresidder Union will be used for a variety of exhibits, including artifacts, photos of jazz greats, tapes of original recordings narrated by Philip Elwood, and a photo essary on the Southern origins of jazz. The display opens Sept. 27 and remains through Nov. 1.

The "Jazz Year" was conceived by a group of Stanford students and is sponsored by Tresidder Memorial Union.

Editors: This story was transmitted on Business Wire 9/20/65.

Stanford University today appointed a noted biochemist to the board of directors of the Palo Alto-Stanford Hospital Center.

He is Dr. Alejandro Zaffaroni, president of Syntex Laboratories in Palo Alto. Dr. Zaffaroni will fill the vacancy of Burton W. Roberts who resigned earlier this year to assume new duties in Minneapolis, Minn.

Two other board members were reappointed to three-year terms. They are Robert H. Klein of Portola Valley, and H. E. Robison of Atherton.

Announcement of the appointments was made by Stanford University President J.E. Wallace Sterling at the annual meeting of the Hospital corporation in Palo Alto. The Hospital Center is owned jointly by the City and the University.

Dr. Zaffaroni is noted for his work in the field of steroid biochemistry. He received his Ph.D degree in biochemistry from the University of Rochester in 1949 and worked at this institution until 1951 as a National Institutes of Health Research Fellow.

He joined Syntex in 1951 as associate director of biological research. He held consecutively the posts of director of biological and biochemical research, and director of research and development. In 1956 he was appointed executive vice president and in 1961 took over the direction of the United States subsidiary of Syntex Laboratories while continuing as director of its research division.

Dr. Zaffaroni lives with his wife and two children in Atherton..

FOR RELEASE SATURDAY, SEPTEMBER 18, 1965

TAHOE CITY--Patients blinded by detached retinas may some day be helped to see again by machines used to create artificial gravity, two Stanford University researchers reported today.

Professor Max Anliker, an aeronautical physicist, and Dr. Donald Hayashi, clinical instructor of surgery at Stanford University School of Medicine, said they were able to reattach a damaged retina by applying rotary vibration on a model of the human eyeball.

An accepted procedure in treating a detached retina is to keep the patient lying still. After several days, the retina usually falls into position by the force of normal gravity, but in most cases surgery is required to reattach it.

"Reattachment," the investigators reported, "was achieved consistently within approximately 5 to 20 minutes depending on the degree of initial detachment." Their findings were presented at the western section meeting of the Association for Research in Ophthalmology.

The model used in the experiments is a nine-inch plastic human eyeball with a rubber membrane simulating the light-sensitive retina on which the visual image is formed. In the real eye the retina is connected to the optic nerve which carries the image to the brain.

The model is filled with liquid simulating the vitreous humor within the human eyeball. The scientists experiment with small holes torn in the rubber membrane such as can occur to the human retina.

By vibrating the model eyeball at a force of normal gravity, Drs. Anliker and Hayashi have speeded up the settling of the retina. Once a human patient's torn retina has regained its position it can be painlessly "spot-welded" in place by a

MORE

laser beam.

Earlier this year, the Stanford investigators whirled the model eyeball on a centrifuge at a force of two G's--twice the force of normal gravity--and the detached retina fell back into place in 20 minutes.

The scientists consider the vibration results, "a small step further in their research." Eventually, they feel, a combination of motions--whirling, vibrating, or rocking--may prove the best way in treating a detached retina.

The idea for the experiments was born as a result of studies performed on dogs by other investigators. They showed that exposure of the animals to strong vibrations could result in retinal detachments.

"This fact," said the scientists, "suggested that mechanical processes involved in the formation of such retinal separation could be reversed under properly devised conditions.

Drs. Anliker and Hayashi soon plan to test animals in actual repair of detached retinas, and if the tests are successful, on human patients.

An oil portrait of Mrs. Emma Pfeiffer Merner, in whose name a teaching chair was established in the Stanford University School of Medicine, was presented Thursday to Stanford University.

The portrait was presented by her sons, Garfield D. Merner of San Francisco, and Paul M.P. Merner of Palo Alto. The chair honors the memory of Mrs. Merner, whose brother Gustavus and his wife established the Gustavus and Louise Pfeiffer Research Foundation of New York 23 years ago.

The Emma Pfeiffer Merner Professorship in anatomy was established in 1963 by a $500,000 grant from the Pfeiffer Foundation to help meet the crucial need for first quality medical teaching. Similar grants were made to three other institutions.

In accepting the portrait Stanford President Wallace Sterling commented, "The portrait, placed as it will be in the School of Medicine, will make apparent the long-evident concern of these families to be of service to mankind, not least of all through education and the healing arts of medicine."

Dr. Robert J. Glaser, vice president for medical affairs and dean of the Medical School, said that "The Merner Professorship will enable Stanford to attract to its faculty a distinguished teacher-scholar who will have a major role in the education of tomorrow's physicians--physicians who will be able to translate effectively the burgeoning knowledge in medical science to the benefit of the sick and suffering."

The Pfeiffer Foundation grants grew out of a survey of 87 medical schools, showing a total of more than 800 budgeted teaching posts which cannot be filled, to illustrate "how desperately medical teaching needs to be bolstered."

Mrs. Emma Louise Pfeiffer was born in Cedar Falls, Iowa in 1860, and lived there for 63 years. After the death of her husband, David C. Merner, a pharmacist to whom she was married in 1882, she moved to California in 1923 to be with her family in Palo Alto.

The Merner and Pfeiffer families have had Stanford connections extending over three generations. Mrs. Merner is described by those who knew her intimately as a gracious and lovable woman of strong influence in a family with long matriarchal and philanthropic tradition.

A study of the mechanisms which control epileptic discharge in nerve cells of the brain has begun at Stanford University School of Medicine.

The investigation is conducted by Dr. David A. Prince, assistant professor of neurology, under a $6,875 grant from the Epilepsy Foundation.

Epilepsy is a symptom of brain disease which affects some two million Americans. Some epileptic attacks may be manifest by major convulsions with unconsciousness while others are accompanied by subtle changes in behavior.

"Patients with seizures, however, may have characteristic abnormalities on their brain wave recordings at times when attacks are completely controlled," Dr. Prince said. "This shows that there are mechanisms within the brain which tend to keep the abnormal discharge in check and prevent it from spreading to become a full-blown epileptic seizure."

By inducing epilepsy in laboratory animals, Dr. Prince is studying the mechanisms which limit the spread of the epileptic discharge. Recordings of the electrical activity from within single cells are made through glass tubes whose tips are so fine they cannot be seen with an ordinary microscope.

Such recordings made from normal nerve cells and those involved in the epileptic discharge will provide information about the normal physiology of nerve cells and how it is altered in epilepsy.

The long-term goal of the research is to gain a more detailed knowledge of the cellular processes which are involved in the production and control of epileptic discharge and to apply this knowledge to the problems of patients.

Dr. LeRoy Allen Pesch, 34, professor and chairman of the department of medicine at Rutgers Medical School, has been appointed associate dean and professor of medicine at the Stanford University School of Medicine. The appointment was announced today by Stanford University President J. E. Wallace Sterling.

Dr. Robert J. Glaser, vice president for medical affairs and dean of the medical school, said "Dr. Pesch's appointment represents an extremely important step forward in strengthening our over-all program in medical education. His experience in the problems of modern medical education will represent an invaluable asset to Stanford Medical School. As associate dean, Dr. Pesch will have major responsibility for all aspects of student affairs and will occupy an important liaison position between students and faculty."

Dr. Pesch was graduated from Iowa State University in 1952. He received his medical degree with honors from Washington University School of Medicine in 1956, and interned at The Barnes Hospital in St. Louis, Mo. He was assistant resident in medicine at Grace-New Haven Community Hospital from 1959 to 1960, and a clinical fellow in medicine at Yale University School of Medicine from 1960 to 1961. From 1961 to 1963, Dr. Pesch served as director of the Liver Study Unit and assistant professor of medicine at Yale University. In 1963, he joined the faculty of Rutgers Medical School.

His publications include more than 30 papers, most of them dealing with the influence of steroids on carbohydrate metabolism and with the mechanisms of liver damage.

Dr. Pesch is also physician-in-chief of Rutgers Medical Service at St. Peter's General Hospital, at New Brunswick, N.J., and consultant in internal medicine to the U.S. Veterans Administration at Lyons, N.J.

He holds memberships in the medical honorary society Alpha Omega Alpha, the Society of Sigma Xi, the American Association for the Study of Liver Diseases, American Federation for Clinical Research, and the American Society of Biological Chemists.

Dr. and Mrs. Pesch have three sons.

Dr. Samuel L. Kountz, who developed a new technique of detecting and treating rejection of kidney transplants at the Stanford University School of Medicine, will leave Oct. 29 for the United Arab Republic to become visiting professor of surgery at the University of Alexandria School of Medicine.

Dr. Kountz was invited to spend three months contributing knowledge on the immunology of renal transplantation under the Fulbright program of educational exchange between the United States and the United Arab Republic. The purpose of the program is to increase understanding between the two countries through the exchange of students, teachers, lecturers and research scholars.

Dr. Kountz currently serves as instructor of surgery at the School of Medicine. He was named the "Outstanding Young Investigator of 1964" by the American College of Cardiology for discovering that kidney transplant rejection begins in the tiny blood vessels known as capillaries. Physicians had previously thought damage began in the kidney cells.

A native of Lexa, Arkansas, Dr. Kountz obtained his B.S. degree in 1952 at Arkansas Agricultural, Mechanical and Normal College in Pine Bluff. He earned his M.S. degree in 1956 at the University of Arkansas in Fayetteville, and his M.D. degree in 1958 from the University's medical school in Little Rock.

Dr. Kountz interned at the Stanford University hospitals in San Francisco and then became an assistant resident and Bank of America Giannini Fellow in surgery at the Stanford Medical School. In 1962 he was a research fellow at the Postgraduate Medical School of London.

He and his wife, Gracie, and their two children reside at 2091 Camino de los Robles in Menlo Park.

Dr. J. G. Scadding, professor of medicine in the University of London and a noted authority on diseases of the chest, will be the first James J. Waring Visiting Professor in the Stanford University School of Medicine.

The annual visiting professorship has been established by the Francis S. North Foundation of Chicago to honor the late Dr. James J. Waring, professor of medicine at the University of Colorado and chief of medicine at Colorado General Hospital for more than 20 years.

Dr. Robert J. Glaser, vice president for medical affairs and dean of the Stanford medical school, said that "the visiting professorship is an appropriate way to honor the memory of a superb clinician and a great teacher. The professorship will be awarded each year to a distinguished physician in the field of chest diseases. We believe that in this and future years the James J. Waring Visiting Professors will make significant contributions to Stanford's educational program in this important field of medicine."

Those named to the professorship will spend equal time at the University of Colorado School of Medicine, the length of service at each school depending on the wishes and schedule of the recipient.

Dr. Scadding will be in residence at Stanford from October 19 to 29. He will conduct ward rounds, work with medical students and house staff, and be available for staff consultations.

He will give a lecture Tuesday, October 19, at 8 p.m. on "Current Concepts of Sarcoidosis," a disease of unknown cause affecting mostly young adults, involving lymph glands, lungs, skin, bones, and other parts of the body. The lecture will be in Room M106 and is open to all physicians in the community.

-MORE-

Dr. Scadding also will chair a panel at the postgraduate course on "The Evaluation of Pulmonary Function," Friday, October 29, at 9 a.m. in Room M106. The course is sponsored by the American Thoracic Society, Tuberculosis and Health Association of California, California Thoracic Society, and the schools of medicine of Stanford and University of California.

Dr. Scadding received his medical education at Middlesex Hospital Medical School in 1932. From 1935 to 1945 he served as first assistant in the department of medicine of the British Postgraduate Medical School of London, and as a senior lecturer from 1946 to 1962. He also served as dean of the Institute of Diseases of the Chest at Brompton Hospital in London from 1946 to 1960, and was its director of studies from 1950 to 1960.

He is a member of numerous learned societies including the Association of Physicians, Thoracic Society, Medical Research Society, and British Tuberculosis Association of which he is past president.

Major gains toward understanding and control of psoriasis, the disfiguring skin disease which afflicts about 4 to 6 million Americans, were reported today by a medical research team from Stanford University.

The findings were contained in a progress report to the John A. Hartford Foundation of New York, which said it would extend the psoriasis probe at Stanford for another three years.

Ralph W. Burger, president of the Foundation, announced that the study would continue under a $299,650 grant to the School of Medicine. The research in psoriasis was launched at Stanford in 1959 and has been carried on with Foundation support totalling $789,571.

At present the cause of psoriasis is unknown. The disease produces reddened, scaly spots or patches. The patches usually occur over the elbows, knees, scalp and back; at times they may cover the entire body. The condition is not painful or severe enough to cause disability in many cases, but it can be unsightly and cause embarrassment, especially in women concerned about their skin.

Stanford researchers have studied 1,500 patients so far to learn more about the cause of the illness, what its specific characteristics are and how it relates to other diseases. New drugs and new ways of administering them have been tried.

The results show that there are influences in the incidence of psoriasis related to age, family, race, and locality, the investigators reported. They indicate specifically that:

. the incidence of the disease is slightly higher in women than men.

. psoriasis occurs more commonly in the white population and the incidence is much higher in Europe and the United States than in Africa.

. although psoriasis may be present at birth, its peak attacks on women occur between the ages of 21 and 25 years, and in men between 26 and 30 years of age.

. the disease appears less frequently in the American Negro and many of these cases occur in children of interracial marriages. It is absent in American Indians.

-MORE-

. there are seasonal variations in the course of the disease, with most patients getting worse in the winter, and better in the summer with sun exposure, and

. thirty percent of the patients had relatives with psoriasis indicating a probable link through inheritance.

Dr. Eugene Farber, head of the department of dermatology and director of the study, said emotional factors figured prominently in aggravation of psoriasis. Thirty-nine percent of the patients stated that the disease appeared at times of worry and 37.2 percent said it worsened during stress.

The research also confirmed a strong link of psoriasis to arthritis. Of the patients studied, 24.5 percent had arthritis of various joints, and 58.9 percent said psoriasis had preceded arthritis.

Detailed information concerning the patients under study was obtained directly from patients seen in the Stanford University Clinics and through questionnaires filled by physicians of dermatological clinics across the country, Venezuela, and South Africa. Close contact was also established with medical services of the Division of Indian Health in South Dakota, New Mexico, Alaska, Montana, Oklahoma, Arizona, and Oregon.

In addition, the Stanford investigators conducted a study in the Fiji Islands, where groups of native islanders and English whites were compared. The results showed an incidence among the whites comparable to whites elsewhere while no cases of psoriasis were found in native Fijians.

The Stanford research team reported that crude coal tar applications and simultaneous exposure of the skin to ultraviolet light still represent the most satisfactory treatment for most cases of psoriasis.

Drugs, such as corticosteroids, given orally have a profoundly immediate beneficial effect, but when the drug is discontinued a large number of patients had a recurrence of psoriasis, far more extensive and severe than before treatment was started.

"We believe that potential basic advances coming from trials of many new agents so far as cure is concerned are limited," Dr. Farber said. "Therefore, our efforts are being concentrated in fundamental laboratory investigation. It is our hope that this approach will provide a sound basis toward ultimate cure of psoriasis."

Such efforts include laboratory studies using techniques of biophysics, physiology, immunology, electron microscopy, and growth of tissue in test tubes. Other areas of investigation concern aspects of skin physiology including skin temperature, studies of DNA synthesis and other biochemical mechanisms.

One of these concerns a specific amino acid, histidine. Stanford investigators have demonstrated histidine to be concentrated at the site of formation of the protective horny layer of the normal skin, a process that is defective in psoriasis.

Working with Dr. Farber are Dr. Alvin Cox, professor of pathology, and other specialists in biochemistry, physiology, genetics, chemistry, and rheumatology.

The Palo Alto-Stanford Hospital Center was awarded a Certificate of Recognition for outstanding fire prevention practices for the year 1965.

The certificate was one of three presented by the Palo Alto Chamber of Commerce Fire Prevention Committee, in cooperation with the Palo Alto Fire Department Bureau of Fire Prevention. Other winners were Preformed Line Products Company and Fairchild Semiconductor Research and Development Division, both of Palo Alto.

This is the first year the Hospital Center has received the award.

"The certificate will give the Hospital Center added incentive to make every week fire prevention week," commented Hospital Director Dr. LeRoy E. Bates. "We look forward to working with the Palo Alto Fire Prevention Bureau in furthering our fire prevention program."

The certificate was awarded to the Hospital Center after the Fire Prevention Bureau inspected the entire Medical Center and reviewed the fire prevention program which was implemented this year by Frank R. Vitale, assistant administrator and fire marshal of the Hospital Center.

The survey showed that the Stanford Medical Center met the standards for thorough fire prevention measures. This is important in a hospital and medical school complex for patient safety and for meeting the state requirement for licensing.

This year, Hospital and Medical School personnel have taken part in a thorough program of fire prevention training. They have watched fire training films, taken part in fire drills, and attended classes on fire hazards and the use of fire extinguishers.

FOR PM RELEASE TUESDAY, NOVEMBER 16, 1965

Patients who talk normally and rationally while under mild sedation and claim afterwards they "can't remember a thing" are probably telling the truth.

This was demonstrated by preliminary studies into the effects of a common barbiturate, thiopental, on learning and memory. Results of the tests were reported today by Dr. John Bunker, professor of anesthesia at Stanford University School of Medicine. He spoke at the fall symposium of the General Clinical Research Center.

"The fact that light doses of thiopental can produce memory deficits for events occurring under sedation was clearly demonstrated," Dr. Bunker said.

He said the study of thiopental was launched because not enough is known about the effect of drugs on the mind. The tests were conducted at Stanford by Miss Anne G. Osborn, now a graduate student at Harvard University, Dr. Ernest R. Hilgard, professor of psychology, Dr. Leslie M. Cooper, assistant professor of psychology, and Dr. Gilbert Frank, assistant professor of neurology.

The group completed studies on 22 volunteers who were given the barbiturate and given test material to read before and during the drug's influence.

While the effects of the drug varied, Dr. Bunker said, most of the volunteers suffered impairment of learning and memory while under sedation. Some could remember nothing and others remembered a great deal. Even hypnosis could not bring out all these events.

It was further shown, Dr. Bunker noted, that even with a small amount of barbiturate, a decrease in performance and judgment can be observed as long as 18 hours later.

Millions of persons innocently are going about their business--driving cars, flying airplanes, making decisions--unaware that the central nervous system may be impaired by these drugs.

One aspect of the work primarily concerns clinicians themselves--can the anesthetized patient recall what goes on in the operating room?

Thiopental commonly is used to put patients to sleep preliminary to deeper anesthesia for surgery, he said. Physicians have suggested that the conversations among surgeons and operating room personnel may penetrate the patient's consciousness.

Dr. Bunker considers it unlikely that the patient absorbs these remarks. He added that the use of thiopental to explore the mechanisms underlying learning and memory have successfully demonstrated several important points. "It can only be hoped that use of drugs to explore the mind will be widened and continued."

Dr. William Dock, a prominent internist, pathologist, and cardiologist, will give the second John Kent Lewis Memorial Lecture at Stanford University School of Medicine.

He will speak on "Bedside Sound and Pulse Studies of Hearts and Blood Vessels" December 6 at 4:30 p.m. in Room M106.

Dr. Dock is professor of medicine at the State University of New York Downstate Medical Center, with offices in the affiliated Kings County Hospital, and the Veterans Administration Hospital in Brooklyn where he is chief of medical service.

Challenging time-worn concepts of medical practice is a dominant characteristic of Dr. Dock. "You can't pioneer in medicine without getting into trouble," he said once, "and it's no fun if you don't."

At an international symposium, for example, Dr. Dock took a shot at fellow doctors who neglected methylmethanol--also referred to as "MM" and only incidentally as alcohol--as medication. He argued for it as a "proved diuretic, a stimulant of gastric secretion and a dilator of blood vessels, but mainly as the best mind pacifier yet discovered."

At another meeting, Dr. Dock helped tumble the old theory that prolonged bed rest is essential in coronary and obstetric cases. "Man's perversions from normal mammalian and even simian behavior make him the scandal of the biologic world," Dr. Dock said. "He not only walks erect like birds and the anthropoids, but continues to drink milk all his life, to eat eggs, and to make love at all seasons. He uses drugs such as nicotine and caffeine daily, alcohol and cathartics almost as often, sometimes to great excess. . . ."

Finally Dr. Dock made his point: "Absolute bed rest kills more patients than anesthesia and all other drugs."

-MORE-

Dr. Dock spent his boyhood in St. Louis. Here he received a "superior" high school education meaning "no girls and no girl teachers to distract us." His premedical course at Washington University was interrupted by six months of ambulance driving in the French Army in World War I. He received his M.D. from Rush Medical College in Chicago in 1923. After two years as a house officer at Peter Bent Brigham Hospital in Boston, seven months in Vienna, and a year as a resident at Stanford Hospital in San Francisco, he began to move up in the academic world, becoming professor of pathology at Stanford University School of Medicine.

He took a similar post at Cornell University in 1941 and, in 1944, became professor of medicine at Long Island College of Medicine, which was absorbed into the new State University of New York Downstate Medical Center in Brooklyn.

Dr. Dock is the author of more than 160 papers, mostly dealing with cardiovascular disease. He is vice chairman of the committee on research of the American Medical Association, a diplomate of the American Board of Internal Medicine, a Fellow of the American College of Physicians, and member of the Society for Experimental Biology and Medicine, and the American Society for Clinical Investigation.

Still he finds time to pursue his particular interest--ballistocardiography, on which he has written a great deal. In the preface of his Porter Lectures, "Heart Sounds, Cardiac Pulsations, and Coronary Disease," Dr. Dock recalls his ancestors "who for over a century had constantly been ready to move over the hills to undeveloped lands" and concludes: "Thus conditioned not to accept the current dogma, I am unable to resist trying out new ideas and techniques."

The lectures are dedicated to the memory of Dr. John Kent Lewis who died in 1961. Dr. Lewis was professor of medicine and chief of the Stanford Medical Service at San Francisco General Hospital. With his Stanford professors, A. W. Hewlett and George D. Barnett, Dr. Lewis had published some of the early work on vascular sounds, exercise and respiration. He was one of the first to study thyroid hormone in relation to the heart. He was well known for his pioneering studies on heart sounds and cardiac arrhythmias.

FOR PM RELEASE TUESDAY, NOVEMBER 16, 1965

A medical research team at Stanford University has found that medullary cystic disease, a rare but infrequently recognized kidney disease which kills its victims in their twenties, is inherited.

Dr. Thomas C. Merigan, Jr., assistant professor of medicine at Stanford University School of Medicine, said the disease has been traced in five generations of one family whose members live in California and in the Midwest.

"We have found clear evidence of genetic transmission of this condition, and we have been able to define many of its clinical and pathological features," Dr. Merigan said.

Dr. Merigan spoke at the fall symposium on current projects of the General Clinical Research Center at Stanford. His associates include Dr. Kenneth D. Gardner, Jr., assistant professor of medicine, Drs. Sidney M. Goldman and Samuel R. Walker, residents in medicine, and Joan M. C. Bull, a Stanford medical student.

The first evidence that a genetic influence may be involved in the development of the disease was obtained by a curious medical coincidence late in 1964. A 33-year-old man was admitted to the General Clinical Research Center for treatment. The patient was in the final stages of kidney failure, and subsequently a transplant was necessary to save his life. But two of his brothers also had died of kidney failure after short illnesses the year before.

Dr. Merigan and his associates were prompted by this to look further into the medical history of the two brothers. Because their deaths were puzzling to their own physicians, the hospitals in which they had died had preserved their kidneys. Microscopic sections of these kidneys were studied and medullary cystic disease was found.

Subsequently, the Stanford research team traced other members of the family and studied autopsy reports and their medical histories. In addition, the researchers were able to obtain kidney tissue on six diseased members of the family and performed biopsies on two living others who had been affected by the disease.

-MORE-

The pattern of inheritance of medullary cystic disease was traced back to a 32-year-old woman who died just before the turn of the century after a short illness.

"Of the 60 family members studied, 20 had the disease," Dr. Merigan said. "Six are still living. The condition has been recognized in members of the first five generations, and its incidence has followed a pattern of dominant inheritance. The number of affected persons in the first three generations was high. Both sexes were affected equally. One parent of each affected individual had kidney disease."

The average age in which the patients died was 24 years, and they had no symptoms of the disease until they reached an average age of 23, Dr. Merigan reported.

Medullary kidney disease was first described in 1962 by Dr. Maurice B. Strauss, an eminent authority on kidney diseases. He found 18 unrelated patients with the disease.

The disease is characterized by occurrence of anemia, frequent salt-wasting, and progressive failure of the kidney to put out the metabolic waste products. Cysts also are formed in the medulla, or inner zone of the kidney. Death usually occurs in the second decade of life.

There are other types of hereditary kidney disease but two of the most common are the classical polycystic disease and the hereditary nephritis. The former is characterized by large cysts throughout both kidneys, leading to death either in childhood or later in life. The latter is a diffuse inflammation of the kidney associated with the obstruction of the glomeruli, the kidney filters.

Medullary cystic disease, however, is hard to identify at an early age. One purpose of our studies, Dr. Merigan said, is to learn how one can diagnose it before affected persons can have children, and to provide proper genetic counseling.

The General Clinical Research Center, a 31-bed facility within the Stanford Medical Center, was established by a grant from the National Institutes of Health to the School of Medicine. It has its own staff, laboratories, and facilities to provide the best possible conditions for scientists from varied backgrounds to conduct rigidly controlled studies on specially selected patients.

New evidence for establishing an accurate diagnosis of a bleeding condition which accounts for heavy and prolonged menstruation in about 15 percent of women was presented today by two Stanford University obstetricians.

Women who bleed too heavily for six to 10 days beyond the normal five-day menstrual cycle may suffer from irregular or delayed shedding of the endometrium--the tissue lining the uterus, they reported.

Until recently it was widely thought that almost all of the endometrial tissue was shed during the days of bleeding and that healing began from cells in the innermost tissue layer in the uterus.

"Contrary to the prevalent view," the Stanford investigators said, "the tissue lining the uterus is not shed as completely as most people thought. However, despite this lack of shedding, the regrowth of a completely new surface occurs with amazing speed on the fourth day of normal menstruation. This validates the contention that evidence of lack of healing in the uterus after the normal menstrual cycle could establish a diagnosis of irregular shedding."

The investigators are Dr. Charles E. McLennan, professor and executive head of the department of Gynecology and Obstetrics at Stanford University School of Medicine, and Dr. Alf Rydell, now on the staff of the Letterman General Hospital in San Francisco. Their findings appear in the November issue of the journal, Obstetrics and Gynecology.

Drs. McLennan and Rydell said they studied more than 500 tissue samples collected from 76 women who had hysterectomies sometime between the first and sixth day of their menstrual cycle.

-MORE-

They observed that in normal menstruation the loss of tissue lining the uterus was less extensive than many believed it to be, yet a very appreciable fraction of the spongy layer above the innermost tissue in the uterus actually disintegrated and disappeared.

Healing of the uterus commonly occurred on the fourth day, and occasionally on the third day of the menstrual cycle from remaining cells of the spongy layer rather than from the innermost tissue as it was previously thought.

The ability of the uterus to heal itself so miraculously within hours is a tissue phenomenon that occurs nowhere else in the human body, Dr. McLennan said. Complete reorganization of tissue components was evident throughout the endometrial cavity on the fifth day.

Regeneration of the new tissue was found to be triggered by glands responsible for preparing the uterus for fertilization. The ability of these glands to regenerate tissue with great speed also explains the ultimate healing of the irregular shedding surfaces after a delay of several days, the researchers said.

When bleeding persists, the condition can be corrected by surgery, they added.

The research was supported by a grant from the National Institute of Child Health and Human Development.

Multiple heart valve replacement--a rare surgical procedure five years ago--can now be accomplished safely in a single operation, a prominent heart surgeon said today.

Dr. Norman E. Shumway, professor of surgery at Stanford University School of Medicine, said in the past 18 months 28 patients have undergone multiple heart valve substitutions at the Palo Alto-Stanford Hospital Center. The patients ranged from 25 to 68 years of age.

Triple valve replacement was accomplished in three cases, and aortic and mitral valve substitution in 20 others. Four more patients had the mitral and tricuspid valves replaced, and in another the aortic and tricuspid valves were implanted. Of the 28 cases there was one death.

The tricuspid valve controls blood flow between the two chambers of the right side of the heart. The mitral valve lies between the two chambers of the left side of the heart, and the aortic valve lies at the juncture of the heart's main pumping chamber on the left side with the aorta, the body's main trunk artery.

Research at Stanford and other medical centers so far has shown that the tricuspid valve is more often involved in diseases of the heart valves than had previously been recognized. The fourth valve, the pulmonary valve, is seldom affected, Dr. Shumway said.

Dr. Shumway attributes the success of the operation on the methods of pre- and postoperative management of these patients and on the technique used in the operation.

-MORE-

"Basic laboratory studies, bed rest, administration of special medication, and preanesthetic evaluation form the major portion of the patient's preoperative stay in the hospital, usually lasting three and a half days," he said.

During the operation the patient is placed under light general anesthesia. The sequence of replacing the valves is designed to protect the heart muscle from being without blood supply too long. This is done by cross-clamping the aorta and--in the shortest possible time--fit, insert, and suture the aortic valve in position, and then unclamp to re-establish the circulation. Subsequently, the other valves are replaced.

Forty-eight hours after the operation, the patient is placed on anticoagulant drugs. Most patients can walk after the third day. Discharge from the hospital is usually on the 12th to the 14th postsurgical day.

"It has been possible to manage these patients on this basic plan," Dr. Shumway said. "Results have been quite satisfactory with reversal of heart failure and return of the patients to normal or near normal activity."

The artificial heart valve used in the operation consists of a plastic ball inside a metal cage. More than 10,000 patients are alive today with the aid of artificial heart valves, he said.

########

(Mailed November 9, 1965)

Three artificial valves--mitral, aortic and tricuspid--appear on patient's chest film. Stanford Medical School group has performed 28 multiple valve replacements in past 18 months, with one death.

On November 16 from 12 noon to 5 p.m. the Stanford University School of Medicine will sponsor a symposium on "Current Research Projects" conducted at the General Clinical Research Center. The meeting will be in Room M106 of the Medical School Building.

Among the participants will be Dr. Henry S. Kaplan, professor and executive head of the Department of Radiology, who will discuss progress in treatment of Hodgkin's Disease; Dr. Thomas C. Merigan, assistant professor of medicine, who will speak on Medulary Cystic Disease, a new form of hereditary kidney disease, and Dr. John P. Bunker, professor and executive head of the Department of Anesthesia, who will report on the effects of an anesthetic drug, thiopental, on learning and memory.

Dr. Robert J. Glaser, vice president for medical affairs and dean of the medical school, will make the introduction. Dr. John W. Farquhar, program director of the research center, will be the moderator.

Research reports also will be presented on kidney transplantation, aspects of pathophysiology of focal epilepsy, results of combined drug—radiation treatment for head and neck cancer, evidence for progression in the spread of Hodgkin's Disease, and problems of metabolism of a specific amino acid, tryptophan in phenylketonuria.

The General Clinical Research Center, a 31-bed facility in the Stanford Medical Center, was established by a grant from the National Institutes of Health to the Stanford University School of Medicine. It has its own staff, laboratories, and facilities to provide the best possible conditions for scientists from many disciplines to conduct rigidly controlled studies on specially selected patients.

Enclosed is a program, a map, and a return postcard to tell us if you plan to cover the meeting.

A study to determine the difference between normal and abnormal brain cells in epilepsy is under way at Stanford University School of Medicine.

The investigation is conducted by Dr. Florry Proctor, a fellow in neurology, and Dr. Helene Rauch, research associate in medical microbiology, under a grant from the Epilepsy Foundation.

Epilepsy is caused by an abnormal electrical discharge in the injured brain. Its symptoms vary from major convulsions to seizures that can be so mild as to be imperceptible. The mechanisms responsible for seizures are not well defined.

Drs. Proctor and Rauch believe that epileptic seizures may be better understood if one studies the protein constituents of epileptic cells. If epileptic and normal brain cells differ, then this difference may be detected by immunologic methods.

The Stanford investigators have studied rabbits in which epilepsy is induced. The electrical activity in various areas of the brain is then recorded using an electroencephalograph (a brain wave machine) to localize the epileptic lesion.

Subsequently, normal and epileptic tissue is obtained surgically from the rabbits and is used to stimulate production of antibodies in other experimental animals. Antibodies are proteins produced by specialized cells of the body originally to fight off infections, but are also stimulated by injection of other proteins.

Antibodies are remarkable in that an antibody of one design will react with only one type of a protein and with no other. By studying how these antibodies react with normal and epileptic tissue, the Stanford researchers hope to understand the nature of epileptic cells.

In the words of a colleague, William L. Dauterman "wears a soft glove on a strong hand." Put it in another way, Dauterman's career has been characterized by his humanity and his determined devotion to helping the blind and the disabled.

And today, Dauterman, who lost his sight in an accident when he was 12, is closer to his goal than ever before.

His contribution is a new and simple intelligence test which may help blind persons discover their talents for new careers.

As chief of vocational services of the Division of Rehabilitation Medicine at Stanford University School of Medicine, Dauterman's task is to guide disabled persons toward an occupational adjustment. In working with the blind, he had to rely mainly on verbal tests to determine their ability for re-training and employment. His experience told him that verbal tests did not give an objective over-all picture of learning skills. A new test, based on tactile sense, was sorely needed to give precise information on the person.

Dauterman himself recalls a revealing experience he had as a boy after his accident. "I really got my hands involved when I lost my sight and had all that time to kill." As a result he developed hobbies and an unusual interest for manual arts.

"Verbal measurements," Dauterman says, "are entirely out of place for some blind persons, particularly the educationally deprived, those from socially impoverished backgrounds, and those with language barriers. Furthermore, some persons develop a pseudo-verbal facility which leads to questionably high scores on verbal tests while educational deprivation in others causes low scores."

Aided by research psychologist Richard M. Suinn, and research assistants Bernice Shapiro and Emily Garfield, Dauterman worked to find a test that could be especially adapted for adult blind persons. He studied available intelligence tests and found one particularly suited for his purpose. It was the Kohs Block Design Test developed at Stanford nearly 40 years ago by Samuel C. Kohs as a thesis for a doctorate in psychology. The test was subsequently published and has been widely used for measuring intelligence in non-disabled children. The test consists of colored cubes which have to be assembled to make a given design. It scores a person's mental level by testing his ability at problem-solving.

-MORE-

In 1958, a Japanese psychologist, Dr. Yoshikazu Ohwaki, modified the Kohs test for use with blind children. Using fabric instead of colors to make the cube designs distinctive to touch, he found the test to be a very useful clinical tool.

Encouraged by Dr. Kohs, who is now retired and living at Burlingame, and with a substantial grant from the Office of Vocational Rehabilitation Administration in Washington, Dauterman decided to test the Ohwaki-Kohs approach on blind adults. By adding his own refinements, he made the test less frustrating although equally challenging to the blind person and more suitable for a wider range of intellectual capacities than the Ohwaki-Kohs test had been.

For example, to make the cube designs more distinctive to touch, rubber tread was used instead of fabric; the basic designs which are copied by the blind person have been reproduced in relief form on plastic sheets; textures have been reduced to rough and smooth with two colors (black and white) employed for persons who are partially blind; a simpler design has been added for warmups by those who have difficulty grasping the nature of the test.

"So far," Dauterman reports, "more than 200 blind persons have been tested in the San Francisco Bay Area, Seattle, Wash., and Little Rock, Ark. Results of the Stanford and Owhaki-Kohs tests show a promising correlation which encourages us to believe the two tests will prove to have the same predictive value."

A major goal of the research is to relate the test results to the individual's actual progress toward educational and vocational success. "To achieve this purpose," Dauterman said, "blind persons are sought as volunteers to participate in the study."

Dauterman's personal tragedy and lifework have a striking parallelism. He attended the California School for the Blind at Berkeley and graduated from Burlingame High School. He entered San Mateo Junior College, and then Stanford University where he received his A.B. in economics and M.A. in sociology in 1948. After several employment experiences in industry, he went to Kansas to become training and placement counselor for the Division of Services for the Blind. He directed the Kansas Rehabilitation Center for the Blind until 1957 when he was appointed assistant professor at Texas Technological College. In 1960, he joined the Stanford Medical School.

Dauterman, his wife and 15-year-old son live at 2344 Thompson Court at Mountain View, Calif.

A combined course in housekeeping skills and English is the key to employability for 11 Spanish-speaking students enrolled in a new training program at the Palo Alto-Stanford Hospital Center.

Sponsored by the Manpower Development and Training Act, the program is coordinated through San Mateo College. It is designed to help unemployed and technologically disadvantaged persons develop marketable skills.

The 11 trainees at the Hospital Center are from Cuba, Mexico, Bolivia, and El Salvador. They range in age from 20 to 59, and their educational backgrounds vary from the third grade to college. One man was a tamale maker in Mexico and another was a teacher in Cuba.

The present class started November 15 and will complete its training January 7. A second class will begin January 24.

"The students are highly motivated and definitely employable. The only barriers are language and knowledge of a specific skill--and these will be removed by the MDTA hospital program," says John J. Graham, assistant housekeeper and supervisor of the program. Mrs. Alice Mild, executive housekeeper, and Mr. Ernest Hultman, her assistant, also are working with the trainees.

According to Graham, the students receive the same training as the Hospital's regular housekeeping staff. The program lasts 10 weeks and involves four hours of on-the-job instruction, five days a week.

The trainees learn safety rules and sanitary procedures; how to mop, dust, and clean hospital facilities; and how to use and take care of housekeeping equipment.

On-the-job training is followed by two hours of English each day. Miss Nancy Vogeley, instructor from San Mateo College, helps the students understand medical terminology as well as basic rules of grammar.

Three trainees have already been hired by the Hospital Center. "The MDTA program not only helps the students but also benefits the Hospital. We see the program as a source of well-trained employees," notes personnel manager, Jack H. Zuckswerth.

Two other hospitals in the area are conducting similar training programs, Mills Memorial Hospital and Peninsula Hospital.

An X-ray technician at the Palo Alto-Stanford Hospital Center has been selected to join the medical staff of the S.S. Hope on its 1966 goodwill voyage to Corinto, Nicaragua.

Chris Aparicio eagerly awaits the January 8 departure of the United States' famous "floating hospital." "I've always wanted to do something like this, she explains. "I admire what the S.S. Hope is doing and look forward to being part of it."

She also has a special interest in Spanish-speaking people and their culture. Her father was born in Spain, and she can speak Spanish.

The S.S. Hope, entirely supported by private donations, is making its fifth voyage. It has previously docked in Southeast Asia, the South Pacific, and South America.

The ship's staff includes a 30-member nursing and technical team which remains aboard ship for the year-long voyage, and a group of doctors who fly to the Hope for two to four month periods. About 18 doctors participate in the project at a time.

As one of four X-ray technicians, Miss Aparicio will work on board the Hope and in the clinics of Corinto, treating patients and teaching students how to use modern X-ray equipment.

"Teaching is the main purpose of the project," she emphasizes. "We will be giving practical on-the-job training to Nicaragua's medical personnel."

Preparing for the voyage, Miss Aparicio has packed personal supplies to last the year--including five extra large rolls of toothpaste, several bars of soap, and plenty of cosmetics. "Makeup and jewelry are scarce in Latin America, and the people love both, so I'm taking extra makeup and costume jewelry for gifts," she adds.

John C. Dumas, 39, of Minneapolis, Minn., has been appointed deputy director of the Palo Alto-Stanford Hospital Center.

The appointment was announced today by Dr. LeRoy E. Bates, executive vice president and director of the Hospital Center.

Dumas is now staff consultant to the firm of James A. Hamilton Associates of Minneapolis, and assistant professor in the program of hospital administration at the University of Minnesota. He will assume his new duties in February.

Dumas received his bachelor of arts degree from the University of Minnesota in 1949, and the master of hospital administration in 1955. From 1959 to 1963 he was administrator of Minneapolis General Hospital, a 417-bed general hospital with graduate and undergraduate teaching programs affiliated with the University of Minnesota Medical School. He held similar positions at the Hennepin County Mental Health Clinic, and University of Pittsburgh Falk Clinic.

In 1959, Dumas took a post as executive assistant to the vice chancellor of health professions of the University of Pittsburgh. He was responsible for the administration of university-operated hospital and clinics and related medical facilities and he coordinated the planning for a $20 million capital expansion program which included seven hospitals and clinics. He also was assistant professor of medical and hospital administration at the Graduate School of Public Health of the University of Pittsburgh.

He holds memberships in numerous societies including the American College of Hospital Administrators, American Hospital Association, Catholic Hospital Association, and the Hospital Council of Western Pennsylvania. He also serves on the board of directors of Minneapolis General Hospital Research Foundation, and the National Foundation.

For his services to the community, Dumas has received the Distinguished Service Award of the City of Minneapolis.

Dumas and his wife are the parents of five children.

A new edition of a book dealing with congenital heart disease has been published by three faculty members of the Stanford University School of Medicine.

The authors are Dr. Saul J. Robinson of San Francisco, clinical associate professor of pediatrics; and Dr. Herbert L. Abrams and Dr. Henry S. Kaplan, professors of radiology.

The book, CONGENITAL HEART DISEASE, presents the three basic parts of clinical diagnosis of congenital heart disease--history and physical examination, electrocardiogram, and x-rays. The major feature of the book, according to the authors, is "its atlas-type format which summarizes a great deal of information regarding the clinical, electrocardiographic, and radiological manifestations of each cardiac abnormality on one page with appropriate illustrations."

The first edition was published in 1956. Since then the authors have added some 200 new illustrations, and chapters on electrocardiography, angiocardiography, and special procedures and treatment.

Keeping pace with the rapid advances in the field, the book covers the impact of surgery within the heart in recent years as well as new refinements in diagnosis of congenital heart disease. The authors also have contributed many personal ideas and clues about diagnosis and treatment resulting from their experience with cardiac cases.

In addition to his Stanford position, Dr. Robinson is chief of the Division of Pediatric Cardiology at Presbyterian Medical Center in San Francisco. Dr. Abrams is director of the Division of Diagnostic Radiology at Stanford, and Dr. Kaplan is executive head of the Department of Radiology.

FOR IMMEDIATE RELEASE

Dr. LeRoy E. Bates, executive vice president and director of the Palo Alto-Stanford Hospital Center, has been elected president of the Central Coast Hospital Conference.

He succeeds Edward Hawkins, administrator of the El Camino Hospital.

During the past year, Dr. Bates has served as chairman of the organization's cooperative laundry committee, and as a member of the personnel committee.

The Central Coast Hospital Conference, which includes 34 member hospitals from Monterey County to Burlingame, serves as a sounding board for problems affecting member hospitals.

- - - - - -

The promotion of Mrs. Carole E. Profant to assistant director of the Palo Alto-Stanford Hospital Center has been announced by Dr. LeRoy E. Bates, executive vice president and director.

Mrs. Profant has served as management analyst for the past year, assisting department heads and hospital administration in solving organizational problems. She has been responsible for instituting new admitting procedures for patients, and programs to improve record keeping, gathering of statistical information as well as procedures for better use of the hospital's bed complement by the two medical staffs.

Mrs. Profant is a graduate of Mt. Sinai School of Nursing in New York. She holds a B.S. degree from Teachers College in New York City, and a Master of Public Health degree from the School of Public Health at the University of California at Berkeley.

Her husband, Dr. Gene R. Profant, is currently in residency training in medicine at the Hospital Center. They reside at 819 University Avenue in Palo Alto.

NOTE TO EDITORS: Four photos from the display are available from the News Bureau. Prints of other photographs to be shown may be obtained from Michael Klein.

Michael Klein, fifth-year Stanford medical school student who went to Ethiopia last year to gain experience in tropical health, spent time on another project only indirectly related to medicine.

One of the results of this project--a photographic study of Ethiopian people--is on display in the student lounge of the Stanford University School of Medicine. The show will continue through December 20.

In Ethiopia, Klein performed many duties. Although he did not have an M.D., he was a house officer in the 50-bed Ethio-Swedish Pediatric Clinic in Addis Ababa, directed a Rickets specialty clinic, and did research in Rickets which he published in the Ethiopian Medical Journal.

"There is a great shortage of doctors in Ethiopia and the health problems of its citizens are immense, from gastrointestinal diseases to malnutrition," Klein said.

Twenty-five percent of the infants suffer from life-threatening Rickets with chest deformities, Klein said. Rickets is a bone disease resulting from deficiency of Vitamin D. The disease is prevalent because of cultural and anthropological reasons, Klein said. In some tribes, parents confine children indoors until they are able to walk to protect them from evil spirits. As a result they are not exposed to sunlight.

"It is a tremendous problem of health education," Klein said.

To solve it, the Ethiopian government has organized Mobile Child Health Centers manned by trained persons who visit the villages to educate the local people and to set up clinics.

-MORE-

Attendance in these clinics has been especially encouraged by the distribution of UNICEF milk, but the UNICEF milk quota to Ethiopia has been cut down lately and the whole health education program is threatened, he said.

Klein traveled some 10,000 miles in Ethiopia with the mobile health units. Because of his interest in anthropology he took pictures everywhere he went, ranging from his Imperial Highness Haile Selassie, emperor of Ethiopia, to Annuac tribesmen near Sudan.

Klein, whose interest is tropical pediatrics and public health, values his experience in Ethiopia very highly. "The only adverse thing about it," he commented, "is that you can't practice medicine in Africa too long. You are completely cut off from the rest of the profession, and you need frequent rejuvenation in places such as Stanford."

Klein's trip was financed by the Stanford department of pediatrics and the International Pediatric Fund. He supplemented his income by salary paid him by the Ethiopian government for his services.

Klein was accompanied on his trip by his wife, Irina, and the then 10-month-old baby Misha, who now can speak Amharic, the native language. Klein will receive his medical degree from Stanford in June.

"Community Mental Health: Comments on Social Consequences of Scientific Inquiry" will be the topic of the fourth lecture in the series PROGRESS IN MEDICINE at Stanford University.

The speaker will be Dr. Erich Lindemann of Harvard University and visiting professor of psychiatry at Stanford University School of Medicine. He will speak Wednesday at 8 p.m. in Room M106 of the Medical School building. The lecture is open to the public.

An experimental psychiatrist and psychologist, Dr. Lindemann has pioneered studies on how people react to loss and grief and developed a highly original approach to the origin of mental disease in the American community.

Dr. Lindemann's studies have shown that an essential component of emotional crises, such as bereavement, is the transition which is engendered by the change in the social system.

His interest in the changes in the social structure which affect a person's mental well-being began in 1942 when he was called on to aid victims of the Coconut Grove fire in Boston. Six years later, Dr. Lindemann was responsible for establishing the first community mental health center in the United States, the purpose of which was to study those community conditions conducive to mental breakdown. As director of the Wellesley Human Relations Service, a position he continues to hold, Dr. Lindemann focused the program on preventive psychiatry and preservation of mental and emotional health.

Dr. Lindemann also served as head of the West-End Research Project which studied the social and psychological effects of relocation on 2,600 families in the West-End area of Boston as a result of urban renewal.

Born in Whitten, Germany, Dr. Lindemann received his Ph.D. degree in 1922 and the M.D. degree in 1926 from the University of Giessen. In 1927 Dr. Lindemann was appointed research associate in psychology at the University of Iowa.

Prior to going to Harvard as a research fellow in neuropathology, Dr. Lindemann had been actively engaged in the diagnosis and management of severely mentally ill patients. It was during this period of research that he discovered the effects of sodium amytal on the mental functions of the depressed and schizophrenic patient. The popular use of barbiturates in the technique known as narcosynthesis (treatment of neuroses in which the patient recalls his suppressed memories and synthesizes his emotions) stems from his research work.

Since 1935 Dr. Lindemann has been associated with Harvard Medical School and the Massachusetts General Hospital. In 1954, he was appointed to his present position of professor of psychiatry at the medical school and chief of psychiatry at Massachusetts General Hospital.

Editors: This story was transmitted on Business Wire Jan. 27, 1966

Stanford University today proposed that negotiations begin immediately to pave the way for acquiring the City's share in the 437-bed Palo Alto-Stanford Hospital Center.

The proposal was contained in a faculty report transmitted by Stanford University President J. E. Wallace Sterling to Mayor Edward Arnold of Palo Alto and the Hospital Board of Directors. It urged that the University "enter into negotiations with the City Council for purposes of defining mutually acceptable terms whereby the University could acquire the Palo Alto-Stanford Hospital."

"The report represents and states the University's position and hopes," President Sterling wrote. "I hope it will indeed be possible for Stanford University to begin discussions with the City Council at the earliest possible date."

The report was prepared after a seven-month study by the Medical School administration and faculty, headed by Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine.

It stated that Stanford must have a University Hospital with 450 to 500 beds and the usual supporting facilities such as operating rooms and laboratories to support its major effort in medical education, patient care, and biomedical research.

"Both the Palo Alto and Stanford University services of the Hospital presently serve important roles as community health resources," the report went on. "The University is fully cognizant of the importance of assuring adequate beds for use by community physicians. Consequently, as a major and essential agenda item for the proposed negotiations, the University would include exploration of the way in which an outstanding community hospital facility could be assured."

-MORE-

The report noted that if the University did acquire the Hospital, volunteer faculty members, many of whom also serve on the present Palo Alto staff, would continue to have access to the University's facility for hospitalization of patients from the community.

Sterling's letter was in response to a request dated May 10, 1965, from the City, to define the University's interest in taking over the City's share of the Hospital.

A citizens' committee previously had recommended to the Council that "it get out of the hospital business" by leasing the Palo Alto Pavilion and Core portion of the Hospital to accommodate the expanding needs of the Stanford University School of Medicine.

At the same time, a joint owners' committee had recommended that the Hospital operating agreements be revised to give the Hospital Board greater authority in the operation of the Hospital. Last spring, President Sterling asked the City Council to postpone action on the operating agreements until the University could review its long range plans for the School of Medicine.

In his letter to the Hospital Board, Sterling wrote: "Stanford University is indebted to the directors of the Palo Alto-Stanford Hospital Center for their devoted service, and recognizes the difficulties presently faced by the directors in attempting to plan for the future."

The Palo Alto-Stanford Hospital was opened in 1959 when the Stanford University School of Medicine was moved from San Francisco to the Stanford campus. It was built jointly by the City and the University and organized as a nonprofit corporation under the direction of the Board of Directors consisting of 12 members, with the City and the University each appointing half of them.

Medical care in the Hospital is provided by two staffs--the Palo Alto Medical Staff, composed of community physicians many of whom hold faculty appointments, and the Stanford Medical Staff, composed of faculty members of the School of Medicine.

"Call Mrs. Rantz if you have any trouble finding housing."

These are familiar words of advice to new staff members at the Stanford Medical Center.

As housing coordinator for the Palo Alto-Stanford Hospital Center and Stanford University School of Medicine, Mrs. Helen H. Rantz is well known to arriving interns, residents, fellows, faculty and students. She sends housing information to them and answers all their questions.

"I sometimes feel like Dear Abbey," she admits. "In addition to inquiries about housing, their questions range from what to wear to whether or not they should bring their sail boat."

The Medical Housing Office was initiated by Mrs. Rantz's husband, the late Dr. Lowell A. Rantz, professor of medicine and associate dean of the Medical School. "When the new Medical Center was built in 1959, he anticipated the problem of moving an entire hospital staff from San Francisco to Stanford, and I was elected to do something about it," she explains.

Mrs. Rantz set up a temporary housing office which has now become a permanent and unique service. Her duties have even expanded to include "babysitting" a car, three violins and four microscopes left behind by medical staff and their families. "This is part of the fun," she says.

There is only one thing she regrets about her job--she now has a "neurotic" dog who barks whenever the phone rings. The neurosis can be traced to the early days of the housing office when Mrs. Rantz was working at home and receiving dozens of calls per day.

The division of infectious diseases of the Stanford University School of Medicine moved into the new Clinical Sciences Research Building January 3. This is the first Medical School unit to occupy the new building since construction began two years ago.

The Clinical Sciences Research Building is located between the Stanford Hospital Pavilion and the Medical School Building, on the side opposite the fountains.

"Complete occupancy of the new building is expected by the end of March and dedication ceremonies have been scheduled for May 26," reports Robert Shaffer, assistant business manager of the Medical School.

Still under construction, the $6 million building will contain facilities for investigation in anesthesia, genetics, medicine, obstetrics, pediatrics, preventive medicine, psychiatry, radiology and surgery.

It will also include the Lt. Joseph P. Kennedy, Jr., Laboratories for Molecular Medicine where basic research will be undertaken related to causes of mental retardation.

Part of the new building will house facilities supported by the National Aeronautics and Space Administration for research in the fields of space biology and biomedical instrumentation.

The new Clinical Sciences Research Building is the first major addition to the Stanford Medical Center since it was constructed in 1959. It is financed in part by Stanford University's PACE program and by government grants for research facilities.

A serious bottleneck in modern surgery is the shortage of competent anesthesiologists, Dr. E. M. Papper, professor of anesthesiology at Columbia University, told a meeting today at Stanford University School of Medicine.

"With scarcely enough anesthesiologists for routine surgery," Dr. Papper added, complex operations like open heart surgery and brain surgery often require as many as three anesthesiologists, confining them to one operation for a period in which, normally, they would work with several patients."

Dr. Papper addressed a meeting of the committee on anesthesia of the research council of the National Academy of Sciences. The committee, chaired by Dr. LeRoy D. Vandam, clinical professor of anesthesia at Harvard Medical School, met to consider measures for solving the shortage of anesthesiologists in medical practice and research.

Compounding the problem, Dr. Papper said, is the fact that anesthesiologists are responsible for many aspects of patient care beyond the operating room.

These include the supervision of postoperative and other types of intensive care units in hospitals and clinics, long-term treatment in relief of pain suffered by chronically ill patients, prolonged control of respiration of accident victims and those suffering from neurological diseases, and of peripheral blood flow during such drastic therapy as kidney dialysis, and the therapeutic use of hypothermia.

Not only is there a dearth of physicians in the practice of anesthesiology, Dr. Papper said, but young scientists have not been attracted to research in this field.

"The shocking fact is that we don't know any more today about how anesthesia works than they did 120 years ago when Morton first demonstrated it," Dr. Papper said.

"In recent years a new hazard has been added to anesthesia because of the widespread use of drugs and various types of medication whose interaction with different anesthetic agents is not understood, though it is suspected, with some justification, that in some instances the interaction has been fatal.

-MORE-

"Anesthesia is so taken for granted now that almost no patients and few scientists raise questions about it. But there are serious, basic questions and we must have scientists who not only ask these questions, but who will be able to find answers to them."

In his report to the committee, Dr. Papper, who now is serving as principal consultant to the Institute of General Medical Sciences of the National Institutes of Health, said a special NIH advisory committee is being established to assist the Institute in planning, program development, and the review of applications in the broad field of anesthesiology.

Another speaker, Dr. Arthur S. Keats, chairman of the department of anesthesiology at Baylor University College of Medicine, said there are 7,500 full and part time anesthesiologists available for the care of patients in more than 5,000 hospitals, many of which have more than one operating room. Over the past 10 years, 50 percent of all hospital admissions have been surgical, requiring the services of anesthesiologists. Projections for 1975 point to a growing gap between supply and demand for competent anesthesia care.

He added that some 80 medical colleges now exist. Most, but not yet all, have departments or divisions of anesthesiology. All, except perhaps a handful of these, now face critical personnel shortages. Yet, these are the institutions responsible for training more than half the practicing anesthesiologists and all the teachers and researchers in the field.

"The future of this entire area of medical science depends on strengthening these sources of our leadership in teaching and research," Dr. Keats said.

Among those attending the meeting Saturday were Dr. Michael E. DeBakey, chairman of the department of surgery of Baylor University College of Medicine in Houston; Dr. L. D. Vandam, professor of anesthesia at Harvard Medical School; Mrs. Florence McQuillen, executive director of the American Association of Nurse Anesthetists; Dr. Samuel F. Seeley of the division of medical sciences of the National Academy of Sciences, and Dr. J. R. Schofield, associate dean of Baylor University College of Medicine.

Sex hormones administered to rats in infancy have altered their sexual behavior for a lifetime.

These experiments reported Wednesday by a Stanford medical school investigator, mark a fascinating new step in research to solve the puzzle of how hormones affect the maturation of the central nervous system.

Answers, when and if they come, might help humans learn why behavior is permanently affected by early experiences, or more specifically how the central nervous system regulates the pattern of behavior predominantly shown by an individual. They may even explain in part why one person develops a capacity to resist disease while another develops ulcers or migraine headaches under the pressures of living.

Scientists believe that hormones, present during critical periods of development, condition the organism's central nervous system to produce permanent changes in adulthood.

The study was described by Dr. Seymour Levine, associate professor of psychiatry, at a public lecture titled "Progress in Medicine" sponsored by the Stanford University School of Medicine.

"Rats at birth are sexually bipotential and physiologically capable of being either male or female," Dr. Levine said. "Thus far the evidence implicates testosterone, the male sex hormone, as the active substance organizing the sexual control system, both in terms of reproductive cycles and sexual behavior."

He explained that the newborn rat of either sex possesses a common, undifferentiated regulatory mechanism for the cyclic release of the gonadotrophic hormones from the pituitary gland. In the newborn female rat, this mechanism becomes fixed throughout life and controls the ovulation cycle. But in the male, the cycle is broken early in life by the secretions of male sex hormones from the infant testes.

-MORE-

If the newborn male is castrated or the normal secretion of the testes blocked in some other way, the original cyclic pattern of ovulation is retained through adult life, Dr. Levine said. Conversely, if the newborn female receives male sex hormones during the critical period after birth, the original female reproductive cycle is changed into a male pattern.

He said that adult male rats, castrated soon after birth, have exhibited complete female sexual behavior when injected with low doses of female hormones or when an ovary was transplanted. Male rats, castrated in adulthood, showed no response to female hormones.

This lack of response, Dr. Levine explained, demonstrates that the critical period for affecting sexual development in those animals occurs after birth.

The studies, according to Dr. Levine, have well established that reproductive hormones exert a profound influence on the nervous system of the newborn rat. They cause the brain to be organized into a male or female pattern of hormone release. These patterns are part of the "hormonostat" of the central nervous system which controls the rate of hormone production and release or both.

The results are only the beginning of what will eventually be a long list of interactions among the neuroendocrine systems at all stages of animal and human development, Dr. Levine concluded.

Dr. Karl Pribram, professor of psychiatry and psychology, will deliver the third public lecture on PROGRESS IN MEDICINE at Stanford University School of Medicine.

He will discuss "Brain as a Stabilizer of Behavior," Wednesday (January 26) from 8 to 9 p.m. in Room M106 of the Medical School Building.

Dr. Pribram, an authority in areas of research on brain function, will talk about how the brain controls its own input and how this control affects behavior. He has done extensive research on the so-called association areas of the cerebral cortex and on the limbic systems of the brain. He will also discuss his experiments on the regulation of emotions and of motivation by these brain structures.

Dr. Pribram is the co-author of "Plans and the Structure of Behavior," a book concerning the application of cybernetics, information and computer theory to the problem of analyzing behavior. The book reviews current understanding of the similarities between computers and the human brain.

He received his M.D. from the University of Chicago in 1941. Born in Vienna, Austria, Dr. Pribram was trained as a neurosurgeon, neuroanatomist, and neurophysiologist.

The Wednesday night medical lectures are presented as a public service by the Stanford University School of Medicine. Their purpose is to give the community an opportunity to develop informed perspective of the exciting developments in medicine being brought into being in laboratories and hospitals throughout the world.

"Studies in Sexual Differentiation" will be the topic of the second public lecture in the series titled PROGRESS IN MEDICINE at Stanford University School of Medicine.

The lecture will be presented by Dr. Seymour Levine, associate professor of psychiatry, Wednesday (January 19) from 8 to 9 p.m. in Room M106 of the Medical School Building.

Dr. Levine's research interests are in the areas of physiological and behavioral development, including stress, hormones, and varieties of infantile experience, as they affect adult behavior. He will report on his latest experiments showing how certain hormones administered to rats in infancy may alter patterns of sexual behavior for a lifetime.

Dr. Levine came to Stanford from the Institute of Psychiatry at Maudsley Hospital in London, England, where he was a fellow from 1960 to 1962. Before going to England he was an assistant professor at Ohio State University.

Receiving his B.A. in 1948 from the University of Denver, he earned M.A. and Ph.D. degrees from New York University in 1951 and 1952.

The medical lectures were initiated by Dr. Joshua Lederberg, Nobel Prize winning geneticist, "to give an opportunity to leaders in academic medicine to share their own insight and perspective with the community."

The lectures are given each Wednesday during the academic year. Dr. Karl Pribram, professor of psychiatry and psychology, will deliver the third lecture in the series January 26. His topic will be "Brain as a Stabilizer of Behavior."

A Stanford University Medical School team reports successful use of the needle-sharp beam of a linear accelerator to destroy retinoblastoma in infant eyes without damage to the lens or other structures.

Dr. Malcolm A. Bagshaw, associate professor of radiology, and Dr. Henry S. Kaplan, professor and executive head of the Department of Radiology, said that 15 eyes in 10 children with retinoblastoma were treated with radiation from the Stanford medical linear accelerator and followed for 10 years. One of the patients was six years old. All but one child still have useful vision. No deaths have occurred, and no extensions of the tumor beyond the globe have been observed.

The Stanford investigators presented their findings at a recent meeting of the Radiological Society of North America in Chicago.

Retinoblastoma, a malignant tumor of the retina, occurs almost exclusively in children younger than 10. Treatment by photocoagulation has been successful when the lesion is small. The extensively affected eye, however, could not be treated and had to be removed. Radiation therapy is hazardous to the lens. But due to the sharpness of the accelerator beam, damage to the lens is avoided.

Drs. Bagshaw and Kaplan flatly challenged the prevailing practice of removing the eye:

"Given a precise technique of radiation therapy and utilizing a supervoltage device with its tissue-sparing action, it is possible to try at least once to cure the unilateral or even bilateral lesions without proceeding directly to enucleation."

In patients in which both eyes are involved and the tumor is small, the physician should make at least one attempt at radiation treatment before resorting to removal of the worst eye, they urged.

They pointed out only one of the 10 children treated had to undergo an operation for removal of the eyes.

Radiation to each affected eye, according to the Stanford radiologists, should be given at an optimum dose of 5,000 rads over five weeks. Some patients required more than one course of radiation to destroy the tumor.

A limited number of paid parking spaces for persons who want the extra convenience of a shorter walking distance has been set aside near the front entrance of the Palo Alto-Stanford Hospital Center.

The controlled parking program will go into effect Tuesday, January 11, Dr. LeRoy E. Bates, executive vice president and director of the Hospital Center, announced.

The paid parking lot involves 175 parking spaces. More than 1,000 stalls are still available at no charge.

The controlled lot is located northwest of the fountain area, adjacent to the Palo Alto Pavilion. The parking fee is 25 cents per hour.

Dr. William Dement, associate professor of psychiatry and noted researcher in sleep psychophysiology, will inaugurate a continuing new series of public lectures at Stanford University School of Medicine beginning January 12.

Dr. Robert J. Glaser, vice president for medical affairs and dean of the medical school, said the lectures titled PROGRESS IN MEDICINE will feature outstanding members of the Stanford medical school faculty and distinguished visiting professors. They will be given each Wednesday during the academic year from 8 to 9 p.m. in Room M106 of the Medical School Building. Each department is scheduled to offer three to four lectures.

The topic of the first presentation will be "Sleep and Dreaming: The Second and Third States of Existence."

Although the lectures are offered primarily for the community as a public service, Stanford undergraduates may enroll for credit, Dr. Glaser said.

The lectures were initiated by Dr. Joshua Lederberg, Nobel Prize winning geneticist, in the hope of giving an opportunity for leaders in academic medicine to share their own insight and perspective with the community. Dr. Lederberg will present some of the lectures.

"The community has little opportunity to develop informed perspective of the exciting developments in medicine which are being brought into being in laboratories and hospitals throughout the world," Dr. Lederberg said. "Public understanding of these developments is of the utmost importance for intelligent participation in important social decisions.

"These have to do not only with personal and community health and with the public investment in medical research, but also with equally important long range problems such as the world population, the management of artificial and transplanted organs, and the applications of the new knowledge of cell biology and heredity."

Dr. Dement, 37, is regarded as one of the world's three leading investigators of sleep psychophysiology. He became one of the founders of this new and demanding field while he was still a medical student at the University of Chicago in ~~1935~~ 1953. He received his M.D. with honors in 1955 and went on to take a Ph.D. in neurophysiology in 1957. He then began to work independently, chiefly at the Mount Sinai Hospital in New York, and since 1963 at Stanford.

According to Dr. Dement, periods of violent nervous turmoil intimately connected with dreaming occur intermittently during everyone's sleep every night. The connection they may have with mental illness is now being studied at Stanford medical school.

In 1964 Dr. Dement received the $1,500 Hofheimer Prize of the American Psychiatric Association for outstanding research.

Dr. Charles S. Houston, special assistant to the director of the Peace Corps, will describe the Peace Corps volunteer doctor program Wednesday, January 12, at 4:30 p.m. in Room M114 of the Stanford Medical School.

Dr. Houston will also show slides of India taken while he was director of the Peace Corps there from September 1962 to December 1964.

Thursday morning from 8 to 10, he will hold informal conferences with interested individuals in the student lounge of the Medical School.

The Peace Corps expanded its call for doctors in 1964, and the first all-doctor program began last July. The new program makes it possible for married doctors with children to enter as volunteers.

Dr. Houston received his A.B. degree from Harvard, his M.D. from Columbia, and interned in medicine at Presbyterian Hospital, New York. He practiced as a family doctor in Colorado and New England before joining the Peace Corps staff.

Dr. Bruce Stocker, Guinness Professor of Microbiology at the University of London and specialist in the field of bacterial genetics, has been appointed professor of medical microbiology at the Stanford University School of Medicine. His appointment became effective January 1.

"Dr. Stocker's background and interests provide a felicitous combination for the teaching and research activities of the medical microbiology department," noted Dr. Robert J. Glaser, vice president for medical affairs and dean of the medical school.

Dr. Stocker attended King's College in London and received his medical degree in 1940 from Westminster Hospital Medical School of the University of London. After serving in the medical branch of the Royal Air Force, he lectured in the department of bacteriology at the London School of Hygiene until 1953, then became head of the Guinness-Lister Research Unit of the Lister Institute of Preventive Medicine. He was appointed professor of microbiology at the University of London in 1963.

For six months in 1961, Dr. Stocker was a visiting professor in the department of genetics at the Stanford medical school. He gave a series of lectures at Stanford on the relationship of bacterial genetics to infectious disease.

His research and publications have focused on the genetic control of the structure of bacteria, particularly the genus Salmonella, a type of germ that causes typhoid fever, food poisoning and other infections. His current study of the composition of the cell wall of Salmonella has a direct bearing on the capacity of these organisms to cause disease.

Last year Dr. Stocker became one of four "New Generation Ehrlich Prize Winners," an award made by the Ehrlich Foundation of Frankfurt, Germany, for excellence in scientific work in the field of Paul Ehrlich's interests.

Jack Zuckswerth, personnel manager for the Palo Alto-Stanford Hospital Center, has resigned to become wage and salary administrator of the Kaiser Medical Care Entities for the northern California region.

Kenneth Dunkle, employment manager, will be acting personnel manager, Dr. LeRoy E. Bates, executive vice president and director of the Hospital, has announced.

Zuckswerth has been working for the Hospital Center since January 1960 when he started as personnel assistant. He became personnel manager in November 1961.

"Babies, Bubbles, and Disease" will be the topic of the eighth lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

The speaker will be Dr. Marshall Klaus, assistant professor of pediatrics and program director of the Clinical Research Center for Premature Infants at Palo Alto-Stanford Hospital Center. The lecture will be Wednesday (March 2) at 8 p.m. in Room M106 of the Medical School Building. It is open to the public.

Dr. Klaus, an authority on pulmonary physiology in the newborn and the respiratory distress syndrome known as hyaline membrane disease, joined Stanford University School of Medicine in 1964.

Before that he was assistant professor of pediatrics at Western Reserve Medical School and director of pediatrics at Mt. Sinai Hospital at Cleveland, Ohio. He received his B.S. and M.D. degrees from Western Reserve University and his professional training at Babies and Children's Hospital in Cleveland. From 1956 to 1958 he was in private practice as a pediatrician.

Kenneth P. Dunkle has been appointed personnel manager for the Palo Alto-Stanford Hospital Center.

Dunkle joined the Hospital staff in 1963 as assistant credit manager and became employment manager in 1965.

A retired lieutenant colonel in the Marines, he received a bachelors degree in business from Northwestern University, Evanston, Ill., in 1941 and earned his masters of business administration at Jackson College in Honolulu in 1962.

Dunkle and his wife are the parents of five children. They live at 2762 Doverton Square in Mountain View.

The history and epidemiology of hepatitis, a liver disease of national importance, will be the subject of the seventh lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

Dr. LeRoy Allen Pesch, associate dean and professor of medicine, will discuss "Hepatitis: The Problem in a Clam Shell" Wednesday (February 23) at 8 p.m. in Room M106 of the Medical School Building. The lecture is open to the public.

Dr. Pesch, an expert in liver diseases, will report on recent outbreaks of hepatitis which have been associated with the eating of seafood, especially clams.

Before coming to Stanford in 1965, Dr. Pesch was chairman of the department of medicine at Rutgers Medical School in New Brunswick, N.J. He is presently continuing his studies of the mechanisms of liver metabolism and cell damage under a recent grant from the National Institutes of Health.

He received his bachelors degree from Iowa State University in 1952 and his M.D. from Washington University School of Medicine in 1956. From 1961 to 1963, Dr. Pesch served as director of the Liver Study Unit and assistant professor of medicine at Yale University.

For a delightful "bit of old England" the place to visit is the Radiotherapy Division of the Palo Alto-Stanford Hospital Center.

Eight of the Hospital Center's nine radiotherapy technicians are from the British Commonwealth: six from England, one from Scotland and one from Australia. The ninth technician, an American, has been trained by the British staff.

The British influence is easily explained. The United States has a shortage of trained radiotherapy technicians and Britain has a well-qualified supply.

A radiotherapy technician is trained in the use of X-rays and radioactive sources in the treatment of cancer.

According to chief technician Joyce Lawson, Britain has a long tradition of therapy training which is just beginning in the United States. "England has been producing therapy technicians for 50 years. The United States officially began three years ago."

British hospitals and medical schools, Miss Lawson adds, have always placed more emphasis on radiotherapy as a means of cancer treatment. "During the past 10 years, however, radiotherapy at Stanford has developed strongly and now enjoys a position of primary importance in the treatment of malignancy," she notes.

The British Society of Radiographers established a national qualifying examination for radiotherapy technicians about 1936. They made the examination mandatory in 1961.

The National Registry of Radiologic Technologists, sponsored by the American Medical Association, prepared a national examination for radiotherapy technicians in 1963. Although this examination is not yet nationally required, it is a significant step toward training more Americans in radiotherapy and standardizing skills. A few states have already made it mandatory.

Presently, most hospitals in the United States informally train nurses and diagnostic X-ray technicians to give radiotherapy treatments.

-MORE-

The Hospital Center's little British "colony" started nine years ago when Miss Lawson came from Scotland by way of Canada to run the new linear accelerator "cancer gun" at the Stanford Medical School in San Francisco.

At the same time, the newly formed Division of Radiotherapy hired Pat Steed from England as its dosimetrist. No one in this country was trained in dosimetry, which involves determining the appropriate method of radiotherapy treatment.

From then on the British influence snowballed. When the Hospital Center needed more technicians it recruited from Britain's radiotherapy schools.

"Recent graduates are eager to come to the United States, especially to California," Miss Lawson says. "Many of the girls have stayed a couple years, and then returned home, spreading the word about the Stanford Medical Center. The Radiotherapy Division now receives several applications a year."

Contacts in Britain also led to the hiring of physicist Angela Deubert who was working in the radiotherapy field in England. "In the United States, few physicists specialize in radiotherapy; they tend to go into industry or nuclear research," Angela explains.

In 1960, the Hospital Center decided to share its knowledge of radiotherapy with American nurses and X-ray technicians. Under a National Institutes of Health grant, the Medical School set up a year-long training program. Two girls have completed the program. One is now on the staff, and the other is aboard the S.S. Hope. A third technician is presently taking the program.

The trainees take special courses in physics, attend radiology lectures for medical students, are given materials to read and on-the-job training. "We eventually hope to give more lectures and train more students," Miss Lawson says.

On a recent trip to New York, Miss Lawson was surprised to find a similar training program at Mount Sinai Hospital--but then discovered it was organized by a technician who trained with her in Scotland.

One of the many peaceful facets of nuclear age--the application of its knowledge and products in the field of medicine--will be the topic of the sixth lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

The speaker is Dr. Joseph P. Kriss, professor of medicine and radiology and head of the division of Nuclear Medicine. He will speak on "Atoms in Search of Disease: 20 Years after Hiroshima" Wednesday (February 16) at 8 p.m. in Room M106 of the Medical School Building.

Dr. Kriss will tell some of the early history of the medical application of isotopes and will describe some of the latest developments in the field which pertain to diagnosis and treatment of disease.

These developments include improvement of radiation detection equipment, development of radioactive substances that concentrate in particular organs and tissues, and better understanding of the factors necessary to obtain clear pictures that can be interpreted by the physician.

Dr. Kriss received his M.D. from Yale University and has been a member of the Stanford medical school faculty since 1948. Endocrinology and nuclear medicine are among his special fields. He has also been a major contributor in the development of a new curriculum in the medical school.

Sandy, an attractive, exuberant, 17-year-old girl, had collided with disaster last summer as a passenger on the back of a motorcycle that crashed into a ditch.

The crash had thrown her against a tree, breaking her neck. Prompt surgery could not reverse the injury to the spinal cord inside the shattered vertebrae. Most of the motor and sensory nerve function of her arms and legs was gone.

After her recovery from the injuries, Sandy spent eight months in the rehabilitation ward of the Palo Alto-Stanford Hospital Center learning, among other difficult lessons, to use substitutes for the muscles in her arms and legs.

Now 16 conferees in the division of rehabilitation medicine at Stanford University School of Medicine were weighing Sandy's ability to cope with the future. Physiatrists (doctors who specialize in the techniques of rehabilitation medicine), nurses, physical and occupational therapists, the social worker, the vocational counselor, and the neurologist and urologist called in as consultants were summing up their separate views of the patient to decide whether she was ready to leave the hospital.

"She needs a lighter wheelchair for traveling," the occupational therapist told the group, "so someone can help her get in and out of the car, and over the curb."

In the next hour, the medical team measured some of Sandy's problems against her ability to solve them, including her disappointment in a former boy friend, her teen-age acne, the emotional stability of her parents, the size of the doorways in her home (could they be enlarged to accommodate a wheelchair?), her questions about marriage, which one of the physiatrists had answered. Although devoid of sexual sensation, she could become pregnant and bear a healthy child.

Conferences held throughout the patient's rehabilitation are a vivid demonstration of the teamwork that is the basis of modern rehabilitation, says Dr. Daniel J. Feldman, director of the division of rehabilitation medicine. More than that, they show the extraordinary range of the rehabilitation team in meeting the problems of these patients.

Most patients are fighting their way back from a catastrophe--from a crippling accident, or from arthritis, stroke, cerebral palsy, multiple sclerosis, or some other disabling disease which has suddenly cut them off from their work and their place in society.

-MORE-

The rehabilitation specialist who accepts responsibility for the patient at this point, unlike the physician or surgeon who preceded him in the patient's care, is not treating the disease but its consequences, Dr. Feldman said. Physical restoration such as retraining muscles, and teaching the use of prosthetic devices, cannot be separated from other problems overwhelming the patient. How can he meet the staggering financial burden? What will his family do in the meantime? Does he have the mental agility and fortitude to make a different life for himself?

Dr. Feldman's comments reflect the dramatic change of opinion witnessed in the last 15 years by the medical profession about what doctors can do for the disabled.

"When I was in medical school in the late 1940's, we had a defeatist attitude toward these patients," recalled Dr. Harry R. Hahn, a former internist and now a postdoctoral fellow studying the new possibilities in rehabilitation medicine at Stanford. "They could survive a stroke or paralyzing auto accident, and then die of bronchial pneumonia--from lying in bed too long. Even the hip fracture patients could get pneumonia.

"We know now that a stroke patient may get return of function months after his stroke. In those days we didn't get much chance to find out."

The change began with the crusading work of Dr. Howard Rusk and his associates in New York's Institute of Physical Medicine and Rehabilitation, who showed that something could be done to help the irreversibly crippled. Dr. Feldman who worked with Dr. Rusk in New York is one of the converts who is spreading the doctrine that disability is treatable.

It is also significant that three of the five present postdoctoral fellows in rehabilitation at Stanford left careers in other fields of medicine to take up this new specialty, and that Dr. Leslie Knott, assistant professor of rehabilitation medicine, came to Stanford after retiring as chief of the division of chronic diseases in the U.S. Public Health Service.

A look at the rehabilitation rooms during the daytime hours provides evidence of the present attitude. Most of the patients, in wheelchairs, gurneys, or on crutches, are busy exercising and learning how to help themselves.

For instance, amputees and those whose legs are paralyzed (paraplegics) learn to strengthen their arms, so they can lift themselves into a wheelchair and from chair to crutches. Quadriplegics (with little or no voluntary movement in their arms and legs) learn to exercise shoulders, neck, or fingers, so they can use mechanical aids to movement. The goal is freedom to get around on their own.

"Our patient is no longer primarily sick--but different. That's a very subtle point--important for the patient and for the world at large," Dr. Feldman explained. "Because of his disability, he will never be normal. But if we treat him as sick, he will be continually waiting to get well."

Stanford's rehabilitation program is linked closely with other rehabilitation ervices in the community--the Stanford Children's Convalescent Hospital, the Palo Alto Veterans Administration Hospital, and the Crystal Springs Rehabilitation Center in San Mateo. Their directors are on the Stanford faculty, and residents earning certification in this specialty take a six-month tour of duty in each of the four hospitals. Another organization, the Children's Health Council in Palo Alto, cooperates with the division when patients need specialized rehabilitation care.

Because of this cooperation, disabled patients benefit by the sum of all the community resources for rehabilitation, Dr. Feldman said.

Perhaps the most remarkable service the rehabilitation division provides for the patient's future is guidance in seeking a job. Vocational rehabilitation counselor William L. Dauterman is a key member of the team.

The reason we are undertaking this responsibility, Dauterman explained, can be summed up from the disabled patient's viewpoint: "If he is going to live, what is he going to live for? What is he going to do with his restored abilities?"

If the patient is a lawyer, teacher, accountant, someone with professional and intellectual skills, he is likely to return to his former occupation, even if not on a full-time basis. Students can continue their studies with extension courses. But auterman's main concern is the patient who must find another occupation or change his way of doing his former work. The vocational counselor suggests alternatives.

To find out what the patient can do, the vocational counselor may send him to the division's Work Abilities Evaluation Laboratory, a unique testing workshop where the patient performs typical factory or clerical jobs. Recording devices wired to the machinery he uses indicate his speed, accuracy, smoothness of motion, his fatigue, physical difficulties, pain, if any, and boredom.

With the test scores, Dauterman is able to suggest the kind of job the patient should seek and the state agencies that will help him get retraining and employment.

Guided by these several counsels, most patients when they leave the hospital have a pretty good plan worked out. They go back into the world again to face a very different future.

Dr. Henry S. Kaplan, professor and executive head of the department of radiology at Stanford University School of Medicine, has been awarded the French Legion of Honor "in gratitude for his exceptional contribution to the development of Franco-American scientific relations and in esteem for his remarkable scientific work."

The citation and medal were presented on behalf of the French government by Consul General Claude Batault in ceremonies at the University's Faculty Club, Wednesday (February 9) afternoon.

Stanford University President J. E. Wallace Sterling, Dr. Robert J. Glaser, vice president for medical affairs and dean of the Medical School, and Michel Oriano, French cultural attache in San Francisco, were among guests attending the presentation.

The Legion of Honor was established by Napoleon as a military award in 1802. Under subsequent governments, it has often been granted to civilians for distinguished service to France. Within the last two years, it has again become a primarily military award, and civilian presentations are less frequent.

Dr. Kaplan has maintained a close working association with radiotherapy and cancer research groups in Paris and has invited several physicians and scientists to Stanford for additional study and training.

One of the visiting physicians recently organized the Association Medicale France-Amérique to improve relations in medical areas between France and the United States. This organization is sending a group of French physicians to the Medical Center in April.

Dr. Kaplan also has given several lectures in Paris. During his most recent trip last February, he described his research at an international symposium on Hodgkin's disease, a malignancy of the lymph glands.

French scientists are most familiar with his work in experimental radiobiology and radiation induced leukemia.

Dr. Kaplan received his B.S. degree from the University of Chicago in 1938, the M.D. degree from Rush Medical College in 1940, and the M.S. degree in radiology from the University of Minnesota in 1944.

He was a leading figure in the design and use of Stanford's linear accelerator "cancer gun" and is presently continuing work on this and related projects in high-energy radiation treatment of cancer.

Dr. David A. Hamburg, professor and executive head of the Department of Psychiatry, will deliver the fifth lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

He will discuss "Genes, Hormones, and Stress" Wednesday (February 9) at 8 p.m. in Room M106 of the Medical School Building. The lecture is open to the public.

Dr. Hamburg's research has fallen in two major areas. He has investigated the effects of psychological stress on the function of the adrenal and thyroid glands. He has also studied human behavior under stress, especially the ways in which normal individuals cope with very difficult situations.

In 1965, Dr. Hamburg and his associates began a study which focuses on the female sex hormone, progesterone. There is evidence that progesterone and the corticosteroids (hormones secreted by the outer area or cortex of the adrenal glands) may play a significant role in causing the distresses of women during the menstrual cycle, pregnancy, and after childbirth. Other research also suggests many close links between the steroids, brain, and behavior.

Dr. Hamburg came to Stanford in 1961 from the National Institute of Mental Health in Bethesda, Md., where he was chief of its adult psychiatry branch. Before that he was assistant director, then associate director, of the Institute of Psychosomatic and Psychiatric Research and Training at Michael Reese Hospital in Chicago.

He received his A.B. and M.D. degrees from Indiana University and his professional training at Michael Reese Hospital, Yale University and the Institute for Psychoanalysis in Chicago.

Dr. Eugene M. Farber, professor and executive head of the department of dermatology at Stanford University School of Medicine, has been selected by the Israel Academy of Dermatology to give a series of lectures at medical schools in Jerusalem and Tel Aviv from February 11 to 25.

He will be the Academy's second annual Wershaw lecturer. Friends of the late Irving Wershaw, president of Dome Chemicals Company of New York, established a fund in 1965 to send one lecturer from the United States to Israel each year.

Dr. Farber's lectures will focus on laboratory aids and studies in the evaluation of cutaneous blood flow, and two skin diseases--pseudoxanthoma elasticum and psoriasis.

He will also address the medical societies of Jerusalem and Tel Aviv and visit the Psoriasis Care Center at Ein Bokek, near the Dead Sea.

The Palo Alto-Stanford Hospital Center recently honored seven Auxiliary members and six Red Cross Gray Ladies who have contributed 1,000 hours or more of service to the Hospital Center.

The volunteers were guests of the Board of Directors at a dinner preceding the January Board meeting.

Auxiliary members who were honored are: Mrs. Harold Hill, Miss Anne Ramsay, Mrs. Stanley Sharp and Mrs. Sheldon Riveroll of Palo Alto; Mrs. George Ogle and Mrs. Harold Ropers of Menlo Park, and Mrs. Harold Beaver of Los Altos Hills.

The six Gray Ladies are: Mrs. Richard Bridges, Miss Josephine Marshall and Mrs. John Roberts Jr. of Palo Alto; Mrs. John DePew and Mrs. Willard Walker of Menlo Park, and Mrs. Milton George of Los Altos.

More than 1,000 volunteers contribute their services to the Hospital Center including 950 Auxiliary and 80 Red Cross Gray Ladies.

The drastic changes in the care of the mentally sick which culminated in the development of community mental health centers have opened broad new vistas for the psychiatrist of the future, a prominent social psychiatrist said today.

Dr. Erich Lindemann, visiting professor of psychiatry at Stanford University School of Medicine, said that the success of community mental health centers has had two paradoxical consequences. One of these is the great increase in the number of those seeking help.

Many sufferers and others previously not considered amenable to psychiatric treatment began to seek it, Dr. Lindemann said. Couples in marital discord, confused school children whose potentialities were obviously greater than their achievement, misunderstood employees whose joy at work had become replaced with bitterness and inefficiency, clergymen and teachers dissatisfied and frustrated in their profession--all these began to come to the community mental health centers.

And although the psychiatrists have gradually surrounded themselves with many therapeutic assistants, treatment case loads continue to mount far more rapidly than additional psychiatrists can be trained.

Consequently, the success of psychiatry also aroused the long-cherished and wistfully protected notion of prevention, Dr. Lindemann said. Better than treatment would be to diminish the incidence of need. Not that psychiatrists expect the sorrow of life to disappear--aggressions will continue to erupt, wounds will continue to be inflicted. But might not something be done to mitigate the severity or the frequency of the severe reaction?

Psychiatrists plead the importance of security and affection in early mother-child relationships, better schools, better teachers, better playgrounds and more of them. But school board members still are inclined to regard such measures as too expensive or irrelevant, he said.

No one disputes the theoretical importance of stable family life, fidelity in marriage, kindness to children, but the public does not generally think of these things as basic to mental health. In the meantime, our divorce rate rises, the battered-child syndrome appears more frequently, racial intolerance increases, Dr. Lindemann commented.

-MORE-

If these things we psychiatrists have been saying were known to all teachers, would our schools improve, Dr. Lindemann asked. If they were known to all our school board members, would our teachers improve? If they were known to all employers, would work losses recede and profits rise? If they were known to clergymen, would religion move into new roles of importance and meaning? Would this be an effective social approach to prevention?

No one really knows what a "total push" social reform of this kind might accomplish. But it would certainly receive the denunciation of people who consider such measures luxuries, he said.

"We have fairly good evidence now that social change, particularly rapid social change, arouses complicated responses," Dr. Lindemann said. At the individual and at the community level the most dramatic forms are seen in mourning and grieving, but processes resembling grief are seen in many forms of role transition which are required by voluntary or imposed social change.

"It is uncomfortable and often painful to abandon previous roles and to accept new ones which are untried and have different implications for social rewards."

The psychiatrist and his team are not immune to these reactions, Dr. Lindemann said. Our adaptation as we ourselves change from clinical psychiatry to community mental health practice is timely and necessary if we want to avoid the eventual loss of the most significant contributions the community mental health program can make.

He added the psychiatrist must be able from time to time to abandon his traditional leadership role to which he is accustomed and begin to compare notes with clergymen, teachers, politicians, and other community leaders responsible for mobilizing group effort for constructive goals.

Dr. Lindemann's talk was one in the series PROGRESS IN MEDICINE sponsored by the Stanford University School of Medicine.

As an experimental psychiatrist and psychologist, Dr. Lindemann has pioneered studies on how people react to loss and grief and developed an original approach to the origin of mental disease in an American community. He was responsible for establishing the first community mental health center in the United States, the purpose of which was to study those community conditions conducive to mental breakdown.

Dr. Lindemann also served as head of the West-End project, in which some 2,600 families in the West End area of Boston were forced to relocate by urban renewal. Dr. Lindemann and his colleagues conducted a systematic appraisal of the social and psychological stresses involved in relocation.

He is professor emeritus of psychiatry at Harvard Medical School and chief of psychiatry at the Massachusetts General Hospital.

Dr. Bruce Stocker, professor of medical microbiology at Stanford University School of Medicine, has been elected a fellow of the Royal Society of London, Britain's leading scientific society.

Dr. Stocker was elected to the Royal Society for his work in bacterial genetics. He was one of 32 "scientists of distinction" named to the Society this year.

The Royal Society was founded in 1660 under the patronage of Charles II "for the improving of natural knowledge." It represents all physical and biological sciences, and serves as an advisor to the British government on scientific issues.

Dr. Stocker was Guinness Professor of Microbiology at the Lister Institute of Preventive Medicine, University of London, before coming to Stanford last January. He attended King's College in London and received his medical degree in 1940 from Westminster Hospital Medical School of the University of London.

His research has focused on the genetic control of the structure of bacteria, particularly the genus Salmonella which causes typhoid fever, food poisoning and other infections.

Dr. Keith B. Taylor, specialist in diseases of the gastrointestinal tract, will give the tenth public lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

Dr. Taylor will speak on "Border Incidents: Intestinal Absorption and Malabsorption," Wednesday (March 30) at 8 p.m. in Room M106 of the Medical School Building.

He will discuss new research techniques which have increased understanding of the gastrointestinal tract and have suggested ways of effectively treating gastrointestinal disease.

Dr. Taylor is associate professor and head of the division of gastrointestinal medicine at the medical school. He received his M.D. degree at Oxford University, England, in 1955 and came to Stanford in 1963.

One of the Palo Alto-Stanford Hospital Center's many visiting doctors is Graciela Garoffalo, known as "Gigi" (G.G.) to her co-workers in the Department of Radiology.

"Gigi" is here on a grant from the Venezuelan government to study the latest techniques in radiotherapy treatment of cancer. She is on leave from the Oncologico Luis Razetti, the cancer hospital in Caracas, where she is assistant radiotherapist and supervisor of the children's division.

She has spent the last 10 months at the Stanford Medical Center and is leaving in April to spend six months in the chemotherapy division of the Memorial Hospital for Cancer and Allied Diseases in New York.

"Gigi" could speak very little English when she came, but "everyone has been a wonderful help," she says.

Establishment of an artificial kidney unit at the Palo Alto-Stanford Hospital Center was approved Wednesday night by the board of directors.

The new unit will be made possible by a $17,000 gift from the Palo Alto-Stanford Hospital Center Auxiliary.

"It gave the Auxiliary board great pleasure to donate funds to this very much needed project which will benefit Hospital patients and the community as a whole," Mrs. Blake C. Wilbur, president of the Auxiliary commented.

In accepting the gift, Robert H. Klein, president of the Hospital board, praised the Auxiliary for its generous contribution and expressed the hope that others would be encouraged to help with the financial support of special hospital needs.

The Auxiliary contributes 6,000 hours of volunteer service to the Hospital each month. Funds for the artificial kidney program have been made possible through earnings from the Auxiliary's Gift Shop. During the past two years, the Auxiliary contributed $17,000 for the purchase of monitoring equipment for cardiac patients, and $30,000 for the establishment of a blood bank.

The artificial kidney unit will be located in the new Clinical Sciences Research Building of the Stanford University School of Medicine. The program will be under the direction of the urology service of the Stanford medical staff.

Dr. John B. Palmer, who will supervise the new program, said the surgery department of the Stanford medical staff is embarking on an active kidney transplantation program and that the artificial kidney is urgently needed to maintain patients in the best possible condition prior to surgery.

-more-

An artificial kidney is a device that duplicates the continuous blood-cleansing action of healthy kidneys, a process called hemodialysis. This removes wastes and toxins that normally appear in the bloodstream and which could cause death if allowed to accumulate.

The artificial kidney, Dr. Palmer said, will be used for patients who are being prepared to receive a healthy kidney from a related donor; to sustain those who have no related donor prospects and need volunteer donors; and to provide interim care for patients with acute kidney failure due to inflammation or injury.

Until now the technique of peritoneal dialysis alone has been used at Stanford to prepare patients for kidney transplantation. The method consists of injecting a fluid solution into the peritoneum, the thin membrane lining the walls of the abdominal cavity. Impurities in the blood pass through the membrane and are then carried away.

This method is less efficient than the artificial kidney. It forces the patient to be in bed for 48 hours or longer during the dialysis, and the problem of infection of the abdominal cavity is a constant hazard, Dr. Palmer said.

The slower technique of peritoneal dialysis is not always applicable to emergencies involving poisonings when survival is related to the speed with which poison is removed from the body. This can be accomplished quickly with an artificial kidney and, therefore, the whole community will benefit by having the life-saving machine available, he added.

A drug related to cortisone but many times more powerful has proved useful in the treatment of mycosis fungoides, a type of skin cancer usually involving large areas of the body skin, a Stanford medical research team reported today.

Six patients with mycosis fungoides were treated with local application of fluocinolone acetonide, the researchers said. Treatment was effective in all cases and the degree of involvement was proportionately related to the amount of the drug used. No side effects were observed. Improvement was noted for as long as nine months when the ointment was applied on the skin regularly.

The ointment has been prepared for research and is more concentrated than previously used preparations for other skin diseases. It is not yet available for general use.

The researchers emphasized that the drug does not offer a permanent cure, but an effective method for the control of this form of skin cancer.

The report appears in the current issue of Cancer, the journal of the American Cancer Society. Its authors are Dr. Eugene M. Farber, professor and executive head of the department of dermatology at Stanford University School of Medicine, Dr. Alvin Cox, professor of pathology in the department of dermatology, Dr. Jack Steinberg, resident in dermatology, and Dr. Richard McClintock, a postdoctoral fellow in dermatology.

Until now the most effective method for treating mycosis fungoides has been radiation therapy. However, recurrences are the rule in this persistent disease and radiation treatment has its limitations for patients who have received extensive doses. In contrast, the ointment can be applied repeatedly, the investigators said.

Although steroid drugs have been known to inhibit mycosis fungoides when taken internally, the researchers made their discovery while studying ways of reducing the inflammation produced by electron-beam therapy in patients with this form of skin cancer.

We noted that several patients treated topically with a concentrated preparation of the drug exhibited unusually rapid regression of the cancerous lesions, they said. Following this lead, local treatment was given to six patients and improvement became apparent.

The researchers noted that treatment of each patient with the drug is an individual problem. Some patients may require highly concentrated drug preparations. Others may respond to weaker doses. After the skin's first response to the treatment, application of the ointment in selected areas once or twice weekly may suffice for the maintenance of improvement.

An oil portrait of Dr. Victor Richards, 47, a distinguished San Francisco surgeon and clinical professor surgery at Stanford University School of Medicine, was unveiled here recently.

The portrait, honoring Dr. Richards for his contributions to the School of Medicine, will be hung in the Lane Medical Library along with those of other distinguished Stanford medical school faculty members. Dr. Richards was professor and executive head of the department of surgery from 1955 to 1958, just before the School of Medicine was moved from San Francisco to the Stanford University campus. Dr. Richards is currently chief of surgery at Presbyterian Medical Center, and Children's Hospital in San Francisco.

The portrait was unveiled at a special ceremony at which Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine, presided. Among those attending was Dr. Loren R. Chandler of San Francisco, emeritus professor of surgery and former dean of the medical school, Dr. Emile Holman, emeritus professor of surgery and former executive head of the department, and many of Dr. Richards' colleagues and former associates.

Dr. Glaser paid tribute to Dr. Richards for his many contributions to Stanford and for his accomplishments as a gifted teacher, clinician, and investigator.

Another speaker, Dr. Robert A. Chase, professor and executive head of the department of surgery, said: "It seems entirely fitting that this portrait should hang in the transplanted Lane Library as a constant reminder that our strength comes not alone from the content of great literature but from people who are the foundation of Stanford's strength."

The portrait was made possible by a gift from Dr. Frederick Leet Reichert of Berkeley, emeritus professor of surgery to the Stanford University School of Medicine.

Dr. Richards is author of two books, and more than 100 papers in the fields of surgery, lung physiology, cancer immunology, hyperbaric oxygenation, and organ transplantation.

He was graduated from Stanford Medical School in 1939, and subsequently continued his education at Stanford in the field of general and thoracic surgery. He joined the Stanford faculty in 1943. He is a member of the American Board of Surgery, and more than 20 professional societies.

A unique 40 inch beeswax candle that will burn a lifetime is currently on display at the Palo Alto-Stanford Hospital Center.

The candle is one of 102 entries in the Hospital Center's third annual employee art show. The public is invited to attend the show which will be held through March 22.

Mrs. Star Carter, secretary in the department of anatomy of Stanford University School of Medicine, raised the bees and designed the candle from their wax. She says it took six years to become an expert on bees and develop the idea.

After observing and reading about the insects, she learned to extract honey and to make small candles. The first candles were so successful as Christmas gifts, she began selling them to friends. The next step was creating the 40 incher.

The length of the candle represents a breakthrough in candlemaking. Beeswax candles have previously been limited to 16 inches.

The problem is obtaining a larger sheet of beeswax without a seam. How did Mrs. Carter get her bees to produce a 40 inch sheet of wax? "That's my secret," she says. She hopes to keep it a secret, too, and has applied for a copyright.

To make the candle, she hand rolled six sheets of beeswax each 40 inches long to form a cylinder two inches in diameter. She mounted the candle on a redwood burl and frosted the natural honey color of the beeswax with sparkles of gold.

When the candle burns, it produces a faint honey fragrance and reveals the hexagonal shape of the honeycomb cell structure, forming a lacey pattern around the edge.

In addition, the candle is dripless. Due to its cellular structure, everything burns. "This is the reason a beeswax candle will burn about 400 percent longer than a regular wax candle," Mrs. Carter notes. "The 40 inch beeswax candle should last a lifetime, with normal use," she adds.

-MORE-

XERO COPY XERO COPY XERO COPY XERO COPY

Mrs. Carter calls the candle the "Empress" and envisions it as an elegant decorative accent beside fireplaces or entryways, for weddings, church decorations and various formal arrangements.

The candle was originally designed as a birthday present for her 15 year old daughter. "This is a perfect gift for those who think they have everything," she says.

When she entered the candle in the Hospital Center art show, she made her daughter a duplicate. The original is now selling for $125.

Mrs. Carter started raising bees six years ago. She began with one bee hive and now has ten, which she keeps in the Sacramento Valley. "Insurance rates are too high in the city," she explains.

The bees were kept in Portola Valley for two years with the help of Edward Scoles, assistant to the business manager in the Stanford University Office for Business Affairs, who arranged the lease of a few acres of University property.

"It is fun to have the bees near," she says. "I like to observe them everyday." She now visits the bees on weekends while living in Mountain View.

Her latest aspiration is to establish "rooftop beekeeping" in the city. She thinks a penthouse arrangement would be ideal. "This would eliminate the vandalism problem, which causes the high insurance rates," she says.

A campaign, designed to teach high school students about the dangers of syphilis and gonorrhea as communicable diseases, has been launched in the Mid-Peninsula area by faculty members of the Stanford University School of Medicine.

The program, directed by Dr. Eugene Farber, professor and executive head of the Department of Dermatology, and Dr. Cleve B. Baker, instructor in dermatology, has been given at Woodside, San Carlos and Carlmont high schools. Two more high schools in the Sequoia district, Menlo-Atherton and Ravenswood, will introduce it this month.

Faculty members from the Department of Dermatology have addressed 7,000 students already and expect to reach several thousand more by the end of the current school year.

"In the 1940's and early 1950's venereal disease had declined steadily under the impact of public health measures and the use of penicillin," Dr. Farber explained. "By the end of the latter decade, however, public health officials began to note, with concern, that the diseases were holding their own and later increasing.

"The unfavorable trend has continued ever since. Millions of people have been growing up ignorant of VD, although there are 300,000 cases of syphilis and more than 1,000,000 cases of gonorrhea in the U.S. each year. Every day 10 babies are born with syphilis. One in every five VD patients is a teen-ager."

Antibiotics are still effective against most cases of the disease, Dr. Farber said. He attributes the continuing rise in case rates partly to complacency, ignorance, and changing moral standards. Studies have also shown that homosexual males are rapid disseminators of venereal disease.

Teen-agers are not getting any information from their parents, Dr. Farber said. When a Washington, D.C. public health specialist interviewed 25,000 teen-agers, he found that only one in 22 learned from parents about VD.

Local educators admit that VD was a "touchy area" they tended to shy away from. They hesitated to teach the facts of venereal disease to high school students because they were not sure of parental attitudes or because they felt they had no one qualified to teach the subject.

This concern was transformed into action a little over a year ago by Miss Marjorie Tubbs, the school nurse at Woodside High School. She had been trying to get information on VD into the curriculum, but no one in the administration and faculty felt qualified to teach it. Then Dr. Farber agreed to develop a program suitable for teen-agers.

-MORE-

Miss Tubbs, in a report on the pilot program at Woodside, wrote that she advocated educating students about venereal disease because "teen-agers being seen in health department clinics for the first time often know nothing about the physical, social, and emotional significance of venereal disease," and that "teaching about venereal disease in high school is logical because this reaches the vulnerable group."

The program developed at Woodside has been followed closely at the other Sequoia district high schools. The presentation by Dr. Farber, Dr. Baker or other members of the Stanford dermatology staff is first made to the faculty and the PTA executive board for suggestions. At all schools where the program has been used, letters have been sent first to parents, either asking signed permission for their children to attend or giving them the opportunity to raise objections or exempt their children from the lecture. So far there have been no objections from parents.

Each doctor talks to a class of about 40 boys or girls. He shows slides of the symptoms of syphilis and gonorrhea in the primary stages of infection. He gives information on the bacteriological requirements of the spirochete (which causes syphilis) and the gonococcus (which causes gonorrhea), germs which multiply in the warm, moist areas of the body. Then he shows a 20-minute moving picture called "The Innocent Partner," produced several years ago by the Kansas State Board of Health.

This film is followed by a question and answer period. Groups are kept small so that every student who wants to ask a question will have the opportunity to do so. This makes the program much more time-consuming for the doctors than if they spoke only once to a large group, but the dermatologists agree that the effort is worth while.

Although the program was first limited to seniors at Woodside, it is now offered to juniors and sophomores and being considered for freshmen.

Dr. Baker commended the school administrators for adopting the program. "Our concern is that no boy or girl should risk health and future for lack of information and commonsense advice," he said. "We do not want to create fear about sex. We make it clear that sexual intercourse of itself does not produce disease. Rather VD is a complication of the misuse of sex. For those who have human values regarding sex, venereal disease causes anguish and tragedy."

Members of the Stanford Medical Student Association are sending medical equipment to South Vietnam to help a former president of the group administer medical aid to civilians.

Captain Eli Glatstein, a 1964 graduate of the Stanford University School of Medicine, requested a microscope and medical stains in a recent letter to the student association.

He is stationed in South Vietnam with a civil affairs company assigned to give medical care to refugees.

Captain Glatstein explained that the Army is prohibited by congressional law from using medical supplies for civilian population. He said he could get necessary drugs from U.S. AID (United States Agency for International Development), but "because of the incredible logistical problems involved," could not obtain diagnostic materials.

"The practice of medicine here remains unbelievably primitive," he wrote. "The pathology is astounding.

"Whether one agrees with our presence here or not, these people need medical help from us."

Phil Matin, fourth year student and vice president of the Stanford Medical Student Association, has organized the project of sending a microscope, accessories and medical stains to Captain Glatstein.

Dr. Herbert L. Abrams, a noted radiologist and researcher, will give the ninth lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

Dr. Abrams will discuss "Fats, Rice, and Mystery: The Coronary Arteries in Man," Wednesday (March 9) at 8 p.m. in Room M106 of the Medical School Building. The lecture is open to the public.

One of the most notable of Dr. Abrams research activities is the development of multiplane motion picture diagnostic techniques for determining the nature of heart defects and the extent to which coronary arteries are narrowed thus increasing the chances of heart attacks.

Dr. Abrams is professor of radiology and director of the Division of X-Ray Diagnosis at the medical school. He received his medical degree from the Long Island College of Medicine in 1946 after graduating with the B.A. in 1941 from Cornell University. He joined the Stanford medical school faculty as an instructor in radiology in 1951, served a year as a special research fellow at the National Heart Institute, Lund School of Medicine in Sweden, and was promoted to his present rank at Stanford in 1962.

He is co-author of the book, "Congenital Heart Disease," with two other faculty members of the Stanford University School of Medicine, Drs. Saul J. Robinson, and Henry S. Kaplan; editor and a major contributor to a two-volume work on "Angiography;" and co-author with Dr. Kaplan of the book, "Angiocardiographic Interpretation in Congenital Heart Disease."

J. A. Bereny, Optics Technology (327-6600)

Scientists at Optics Technology, Inc., of Palo Alto, the Stanford University School of Medicine, and Palo Alto Medical Research Foundation have developed a new method of measuring the oxygen in the blood of patients without taking a sample.

The procedure, according to the scientists, represents an important advance in the diagnosis and treatment of cardiac and lung disease where a quick and accurate determination of oxygen saturation of blood is needed.

Conventional techniques require the removal of blood samples from the patient and laboratory results are not immediately available.

Cardiologists often need to monitor oxygen saturation within the heart continuously to determine the presence of congenital cardiac abnormalities. Clinical physiologists also have been interested in recording oxygen saturation in patients with severe pulmonary disease in which several respiratory mechanisms must be regulated.

Researchers at Optics Technology have developed an instrument in which tiny fibers are built into a standard cardiac catheter. These transparent fibers of optical glasses allow light to travel, through an optical phenomenon known as total internal reflection, to the other end of the tube even when the fiber is curved many times.

The catheter is typically 125 centimeters long and 0.23 centimeter in diameter and contains about 100 fibers divided into three optical channels. One channel transmits light from the special source in the instrument to the opposite end of the catheter which is located in the heart, a blood vessel or the lung.

When the light enters the blood it is scattered by the red blood cells, illuminating an area of about three millimeters in diameter around the catheter tip. The two remaining channels in the catheter pick up and return the reflected light to the instrument, where it is detected at two wavelengths and converted into an electrical signal. The signal is amplified and fed into a recorder which computes the ratio and displays it on a chart calibrated directly in percent of oxygen saturation.

The method is based on the principle that chemical compounds absorb light at certain characteristic wavelengths. In blood there is one wavelength, 805 millimicrons, at which light is absorbed equally by the blood protein hemoglobin before and after it combines with oxygen. At another wavelength, 600 millimicrons, the absorption by oxygen-rich hemoglobin is markedly different. From the ratio of these two wavelengths, scientists can estimate how much oxygen is contained in the blood.

-MORE-

The new instrument has been under development by Optics Technology for the past four years. Work for the first three years was supported by a grant from the National Institutes of Health to the Palo Alto Medical Research Foundation. During this period, clinical investigations have been initiated by researchers at the Stanford University School of Medicine.

Principal investigators are Dr. Narinder S. Kapany, president and director of research of Optics Technology, Inc., and Dr. Donald C. Harrison, assistant professor of medicine at Stanford University School of Medicine. Major contributors are Norman Silbertrust, and R. P. Drake of Optics Technology and Harry A. Miller, research assistant in cardiology at Stanford.

The investigators made studies in dogs in which the oxygen saturation of blood was controlled by subjecting animals to gas mixtures containing different amounts of oxygen. Blood samples were removed from these animals and the oxygen saturations were determined by conventional methods. Results showed a close correlation to those obtained with the fiber optics catheter when inserted in the cardiac chambers or blood vessels. The instrument was also used to determine oxygen saturation directly in the chambers of the dog's heart.

After the instrument was shown to be extremely sensitive, stable, and accurate, it was then used in nine patients with congenital cardiac disease, the investigators said.

It was possible to advance the fiber optics catheter through the venus system and into the heart for a continuous recording of oxygen saturation from the pulmonary artery, right ventricle (pumping chamber), right atrium (the collecting chamber on the right side of the heart), and vena cavae (the two main veins conveying blood to the heart), Drs. Kapany and Harrison said.

"Studies of the effects of breathing and various other respiratory functions were made and the oxygen saturation was measured continuously. In each of the eight patients, it was possible to localize the abnormality within the heart accurately. The diagnosis was confirmed by conventional methods in each case."

Other applications of this method have just begun to be explored by the Optics Technology-Stanford team.

It is possible, the investigators said, to determine the concentration of injected dyes within the cardiovascular system with this instrument and, thus, it can be used for continuously recording cardiac output.

The instrument may also be used for monitoring the oxygen input of critically ill patients over long period of time in coronary and intensive care units, and for determining certain chemical compounds within the bloodstream at remote areas of the body such as the kidney and liver.

"It is apparent from the studies made thus far that it is possible to develop a larger catheter with an illuminating system which would allow visualization of the inner surfaces of blood vessels and the heart," the investigators added.

##########

(Mailed March 8, 1966)

Dr. Narinder S. Kapany (left), president and director of research of Optics Technology, Ind. of Palo Alto, and Dr. Donald C. Harrison, assistant professor of medicine at Stanford University School of Medicine, demonstrate use of fiber optics catheter on model of the heart. The instrument can measure oxygen in the blood without taking a sample. The technique represents an important advance in the diagnosis and treatment of heart and lung disease where oxygen saturation must be measured quickly and accurately.

Editors: This story was transmitted on Business Wire March 3, 1966.

Surgeons at the Palo Alto-Stanford Hospital Center today performed a kidney transplant operation on Mrs. Marilyn Mongelli, 33, of 3915 E. Hampton Way, Fresno.

Mrs. Mongelli, a victim of chronic kidney failure, received a healthy kidney from another Fresno woman. The donor was Mrs. Mary Louise Eisentrager, 28, of 3014 N. Spalding. Both donor and recipient are in satisfactory condition, the surgeons said.

Mrs. Mongelli is a patient in the General Clinical Research Center which is supported by the National Institutes of Health.

This was the first time the Hospital Center has performed a kidney transplant operation on human patients who are not related.

The operation was undertaken after detailed screening and testing of the donor, including careful cross-matching of her blood with that of the recipient.

Six other kidney transplants have been performed at the Hospital Center. The first, in 1960, was a transplant between identical twins, which is much simpler than a transplant between others.

The Stanford University surgeons have devised a method to treat the patient with lower and safer dosages of the powerful drugs that help prevent the rejection reaction.

All of their operations have been successful, and the patients have resumed normal activities.

Winners of the Palo Alto-Stanford Hospital Center's third annual art show were recently announced after tallying the votes of 400 viewers.

More than 100 employees, staff members, students and volunteers entered the Hospital Center's March show. First, second and third prize ribbons were awarded in the following categories: painting, photography, drawings, sculpture, mosaics and other.

Margaret Sullivan, staff nurse in the emergency room, won first prize in the painting category for her watercolor, "Woodside Autumn". Dr. Peter Samu, resident in radiology, won a blue ribbon for his color photograph of yellow wild flowers entitled "Dawn," and Mary Elizabeth Stone, research technician in cardiology, won first prize for her mosaic of a fish.

"Reflections of an Asian Nude," a felt pen and pencil sketch by Landrum S. Tucker, fifth year medical student, won first prize in the drawing category. A bronze sculpture by Dr. William B. Pratt, postdoctoral fellow in pharmacology, also won a blue ribbon. Dr. Pratt's entry was titled "Resignation."

For the second year, Dr. Raymond C. Stofer, research associate in surgery, was voted a first prize winner. His popular entry, "It's Raining," was a nickel silver-on-copper figure holding an umbrella.

Maria Carey, admitting clerk, was runner-up in the painting category with her "Mandarin Duck," a watercolor on silk. Other second prize winners include Dr. Richard Woodman, research associate in radiology, for his ink and crayon drawing, "Tripper's 1900;" Dr. Abraham Daniller, resident in surgery, for his terra cotta sculpture, "Barbara-2066;" Elizabeth H. Parker, admitting clerk, for her mosaic, "Spring Bouquet," and Mrs. Sheldon E. Riveroll, Auxiliary, for her "Pink Iris" in resin.

In photography, entries by Dr. Hewlett Lee, Palo Alto medical staff, placed second and third. "Heads Up," a color photograph of a mushroom pushing its head through the earth won second prize, and "Kookaburra Sits in the Old Gum Tree" won third.

Other third prize winners were: Marjorie Arnold, Auxiliary, for her oil "Portrait" of a young girl; Mary Kay Walker, research technician in the division of infectious diseases, for her pen and ink sketch, "California Oak;" Karen Mazik, candy striper, for her terra cotta sculpture, "Compassion," and Carol McGee, senior laboratory technologist in clinical chemistry, for her mobile of different shapes and kinds of woods.

A patient whose transplanted kidney is rejected by the body's immune response can now be saved by a second graft when donors are available, two Stanford University surgeons said today.

An operation of this type was successfully performed at the Palo Alto-Stanford Hospital Center March 23 to save the life of Mrs. Marilyn Mongelli, a 33-year old Fresno housewife and mother of two. She was a patient in the General Clinical Research Center of the National Institutes of Health.

Mrs. Mongelli received a healthy kidney from Mrs. Dani Ferguson, 57, of Costa Mesa. The surgeons, who asked not to be identified, said Mrs. Mongelli is recovering smoothly from the second operation and the new kidney is functioning normally. They expect her to be out of the hospital within two weeks or possibly earlier.

Mrs. Ferguson, an office manager for a Santa Ana firm, said she volunteered her kidney to save Mrs. Mongelli's life after reading newspaper reports of the need for donors. "If my small contribution has furthered the knowledge of kidney transplants I am greatful for the opportunity to be of help to this cause", Mrs. Ferguson said. She was among 60 persons who offered to donate a kidney.

The first kidney was donated by Mrs. Mary Louise Eisentrager, 28, of Fresno. The kidney failed to function, however, due to extreme incompatibility between donor and recipient and was subsequently removed. In the past, rejection was frequently fatal.

The surgeons cautioned that compatibility between donor and recipient is still unpredictable and that new techniques of typing and cross matching donors are needed. It is possible, they explained, to develop methods for typing several thousand combinations of donor and recipient tissue, particulary for the 5 or 6 strong antigens, and to perform operations with the best matches.

Dr. Howard M. Cann, 37, assistant professor of pediatrics at Stanford University School of Medicine, has been awarded a $30,000 grant for teaching and research from the John and Mary R. Markle Foundation of New York.

He is one of 25 medical scientists in the United States and Canada to be appointed a 1966 Markle Scholar in Academic Medicine.

The grant pays $6,000 a year for five years to the medical school where each of the Scholars is a faculty member. It is to be used to supplement salary and aid research.

Markle Scholar grants were established to help relieve the faculty shortage in medical schools by giving support to teachers and investigators early in their careers. Since 1948, the Markle Foundation has appropriated more than $12,800,000 toward the support of 430 faculty members in 88 medical schools.

Dr. Cann is the seventh member of the present Stanford faculty to receive this award. The others are: Drs. Frederic Eldridge, associate professor of medicine and head of the division of pulmonary physiology; Herbert Hultgren, associate professor of medicine and head of the division of cardiology; Guy McKhann, associate professor of pediatrics and medicine; Stanley Schrier, associate professor of medicine; Herbert Schwartz, associate professor of pediatrics, and Francis Yates, associate professor and acting head of the department of physiology.

Before joining the Stanford faculty in 1963, Dr. Cann was a senior postdoctoral fellow in the Institute of Genetics at the University of Pavia in Italy. In 1956, he was a resident in pediatrics at the Stanford Medical School in San Francisco, and from 1960 to 1962 was a postdoctoral fellow in Stanford's Department of Genetics.

Dr. Cann received his B.A. in chemistry in 1950 and his M.D. in 1954, both from the University of Colorado.

Winners of the Palo Alto-Stanford Hospital Center's third annual art show were recently announced after tallying the votes of 400 viewers.

More than 100 employees, staff members, students and volunteers entered the Hospital Center's March show. First, second and third prize ribbons were awarded in the following categories: painting, photography, drawings, sculpture, mosaics and other.

Margaret Sullivan, staff nurse in the emergency room, won first prize in the painting category for her watercolor, "Woodside Autumn". Dr. Peter Samu, resident in radiology, won a blue ribbon for his color photograph of yellow wild flowers entitled "Dawn," and Mary Elizabeth Stone, research technician in cardiology, won first prize for her mosaic of a fish.

"Reflections of an Asian Nude," a felt pen and pencil sketch by Landrum S. Tucker, fifth year medical student, won first prize in the drawing category. A bronze sculpture by Dr. William B. Pratt, postdoctoral fellow in pharmacology, also won a blue ribbon. Dr. Pratt's entry was titled "Resignation."

For the second year, Dr. Raymond C. Stofer, research associate in surgery, was voted a first prize winner. His popular entry, "It's Raining," was a nickel silver-on-copper figure holding an umbrella.

Maria Carey, admitting clerk, was runner-up in the painting category with her "Mandarin Duck," a watercolor on silk. Other second prize winners include Dr. Richard Woodman, research associate in radiology, for his ink and crayon drawing, "Tripper's 1900;" Dr. Abraham Daniller, resident in surgery, for his terra cotta sculpture, "Barbara-2066;" Elizabeth H. Parker, admitting clerk, for her mosaic, "Spring Bouquet," and Mrs. Sheldon E. Riveroll, Auxiliary, for her "Pink Iris" in resin.

In photography, entries by Dr. Hewlett Lee, Palo Alto medical staff, placed second and third. "Heads Up," a color photograph of a mushroom pushing its head through the earth won second prize, and "Kookaburra Sits in the Old Gum Tree" won third.

Other third prize winners were: Marjorie Arnold, Auxiliary, for her oil "Portrait" of a young girl; Mary Kay Walker, research technician in the division of infectious diseases, for her pen and ink sketch, "California Oak;" Karen Mazik, candy striper, for her terra cotta sculpture, "Compassion," and Carol McGee, senior laboratory technologist in clinical chemistry, for her mobile of different shapes and kinds of woods.

A patient whose transplanted kidney is rejected by the body's immune response can now be saved by a second graft when donors are available, two Stanford University surgeons said today.

An operation of this type was successfully performed at the Palo Alto-Stanford Hospital Center March 23 to save the life of Mrs. Marilyn Mongelli, a 33-year old Fresno housewife and mother of two. She was a patient in the General Clinical Research Center of the National Institutes of Health.

Mrs. Mongelli received a healthy kidney from Mrs. Dani Ferguson, 57, of Costa Mesa. The surgeons, who asked not to be identified, said Mrs. Mongelli is recovering smoothly from the second operation and the new kidney is functioning normally. They expect her to be out of the hospital within two weeks or possibly earlier.

Mrs. Ferguson, an office manager for a Santa Ana firm, said she volunteered her kidney to save Mrs. Mongelli's life after reading newspaper reports of the need for donors. "If my small contribution has furthered the knowledge of kidney transplants I am greatful for the opportunity to be of help to this cause", Mrs. Ferguson said. She was among 60 persons who offered to donate a kidney.

The first kidney was donated by Mrs. Mary Louise Eisentrager, 28, of Fresno. The kidney failed to function, however, due to extreme incompatibility between donor and recipient and was subsequently removed. In the past, rejection was frequently fatal.

The surgeons cautioned that compatibility between donor and recipient is still unpredictable and that new techniques of typing and cross matching donors are needed. It is possible, they explained, to develop methods for typing several thousand combinations of donor and recipient tissue, particulary for the 5 or 6 strong antigens, and to perform operations with the best matches.

(more)

Until methods for tissue typing are developed, the use of several donors can make long-term survival of kidney patients possible. "We don't have to lose a patient because the kidney is rejected," the surgeons said.

At present tissue matching is by major blood groups. If a graft fails, another can be tried later. The patient has to be carried by a kidney machine until another kidney becomes available.

Anti-rejection therapy is based on drugs. A monitoring technique, developed at Stanford over a year ago, enables physicians to treat the patient with safer dosages than previously possible. Higher dosages of these drugs could result in severe infection because of the depressing effect on the bacteriological defenses of the body.

The Mongelli-Eisentrager-Ferguson transplants were the first done at the Center between unrelated patients. Six kidney transplants have been performed between relatives since 1964. All of them have been successful.

Stanford University School of Medicine recently announced the appointment of John W. Hornback as resident architect.

Hornback joins the Stanford staff with four years experience as project architect for the University of California at Santa Cruz. He is presently coordinating final stages in the occupancy of the School of Medicine's new Clinical Sciences Research Building and planning the renovation of vacated areas.

Prior to his appointment at Santa Cruz, he was employed in the Office of Architects and Engineers at the University of California at Berkeley. He was graduated from the University of California at Berkeley with a master of arts degree in architecture in 1954 and became a licensed architect in 1960.

Hornback, his wife and four children are now living in Capitola. They plan to move to the Palo Alto area this summer.

Dr. Bernard W. Nelson, 30, has been named assistant dean for student affairs at Stanford University School of Medicine. The appointment was announced by Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine.

Dr. Nelson will concurrently occupy the position of instructor in basic medical sciences in the Max C. Fleischmann Laboratories. He joined the Stanford faculty in September 1965 as an acting instructor.

The new assistant dean received his A.B. degree with distinction in 1957 and his M.D. in 1961, both from Stanford University. He was a postdoctoral fellow in Stanford's Department of Medical Microbiology from 1961 to 1965 and is a member of the Alpha Omega Alpha honorary medical society.

Dr. and Mrs. Nelson and their three children live at 135 La Sandra Way, Menlo Park.

Dr. George W. Thorn, a noted authority on endocrine disorders, will be the Charles D. Armstrong Visiting Lecturer at Stanford Medical Center June 2 through 7.

Dr. Thorn will participate in medical conferences and seminars during the visit and will give the annual Charles D. Armstrong Memorial Lecture Friday (June 3) at 8 p.m. in Room M106 of the Medical School Building.

His topic will be "The Approach to Patients with Adrenal Hyperfunction."

Dr. Thorn is Hersey professor of theory and practice of physic at Harvard Medical School and physician-in-chief of the department of medicine at Peter Bent Brigham Hospital in Boston. His book, "The Diagnosis and Treatment of Adrenal Insufficiency," is considered a classic in medical literature in enriching knowledge of the functioning of the adrenal glands and the chemical manifestation of endocrine disorders.

Dr. Thorn's career is replete with honors. He won twice the American Medical Association's Gold Medal, and is recipient of the Chancellor's Medal of the University of Buffalo, the U. S. Pharmaceutical Manufacturers Association Award and the Alvarenga Award. He is a Fellow of the American College of Physicians and member of numerous societies, including the American Society for Clinical Investigation, and the American Physiological and Endocrine societies.

He was graduated from the University of Buffalo School of Medicine in 1929.

His visit is sponsored by the Charles D. Armstrong Memorial Program of the Palo Alto medical staff and the department of medicine of the Stanford medical staff of the Palo Alto-Stanford Hospital Center. Dr. Armstrong was a co-founder of the Menlo Medical Clinic and chief of staff of the Palo Alto Hospital in 1956-57.

FOR PM RELEASE, THURSDAY, MAY 26, 1966

The existence of private universities is threatened by ill-defined relationships with the government, and by competition from tax-supported institutions for private gifts, Tulane University President Herbert E. Longenecker warned here today.

Dr. Longenecker said that as a result of Medicare, Heart-Stroke-Cancer and other federal legislation "clear concepts of relationships between universities and the government will be needed."

He spoke at ceremonies marking the opening of the new $6 million Clinical Sciences Research Building at Stanford University School of Medicine. His topic was "Public and Private Partnership for Medical Progress."

"Expansion of the relationship to the extent forecast by legislation already enacted can mean only the inclusion of many more federal dollars in both the operating and the capital budgets of medical schools," Dr. Longenecker said.

"What must be kept in mind, however, is that federal dollars are available to the institution not only for its aid and encouragement but for the accomplishment of specific and mutually agreed on tasks. The additional fact is that most federal dollars require the assignment of precious and limited dollars procured elsewhere and available for general institutional purposes."

This requirement for the "matching" dollar has been in all the federal legislation related to facility funds, Dr. Longenecker said. In program support funds, however, governmental policy has vacillated.

"The executive branch of the federal government has repeatedly recognized the validity of the university's claim for reimbursement of all costs without gain or loss," he said.

-MORE-

"Congress, however, has seen fit at times to legislate arbitrary limitations on certain aspects of cost and most recently has directed a compulsory 'cost-sharing' approach which each agency of the government is trying to implement in an infinite variety of interpretations that add more unreimbursed cost to the university's expense."

President Longenecker implied that this policy puts the private university at a distinct disadvantage compared with the public universities.

For the private university, the matching dollars have come from essentially the same kind of sources that traditionally have founded them and nurtured their growth --namely private gifts of individuals, business firms, and foundations, he said. The publicly supported institutions have had access to state taxes, and in addition have accelerated their programs designed to increase their support from private sources.

Dr. Longenecker said while he is sympathetic with those state institutions whose funds from state taxes are held below their needs, the fact remains that the supply of private resources is not limitless. A great allocation of private dollars to support the public institution means just one thing--a lesser share for the private institution.

He expressed regret that in many quarters today only lip service is paid to the notion that the real strength of American higher education lies in the diversity of its institutions.

"If indeed there were conviction on this point we would scarcely be witnessing the enormous development of public institutions and the continued trend toward conversion of private colleges and universities to public status," Dr. Longenecker said.

He noted that only in the United States has private motivation to philanthropy been encouraged by public policy.

"Any public and private actions which in effect diminish the role of these private institutions can be expected to lead only to an ever expanding dependence upon the taxing power of government with all its limitations and competitive interests," he said.

Man's search for life on other planets--and for an end to the tragic problem of mental retardation on earth.

These and other quests are combined in the new Clinical Sciences Research Building of the Stanford University School of Medicine scheduled to be dedicated at 2:30 p.m., Thursday, May 26.

The building, representing an investment of more than $6 million, will be devoted to research into yet unconquered illnesses, and will serve as an essential element in medical education at Stanford University, according to Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine.

It is the first major addition to the $22 million Stanford Medical Center since it was completed in 1959.

Stanford's medical curriculum emphasizes the unity of biology and the basic medical sciences and the interdependence of medicine with other university disciplines.

"The School of Medicine carries on a major portion of its comprehensive teaching program in the Palo Alto-Stanford Hospital Center and the Stanford University Clinics with exemplary patient care as a key objective," Dr. Glaser commented. "The new facility will enable the student, working side by side with the experienced scientist, to acquire the inductive investigatory technique he will utilize throughout his professional career.

"Whether he elects to serve society as a family physician in a small town, as a specialist in an urban center, or as an investigator seeking answers to yet unsolved problems, we hope he will remain 'a perpetual student' of medicine so as to give his best to society. Research experience is an invaluable part of the student's education.

"The completion of the new building is a major chapter in the history of the Stanford University School of Medicine, enabling the present faculty to carry forward the tradition of leadership established by its distinguished predecessors in the School's first half century." (See background story attached.)

Along with the creation of substantial new space, there has been supplied some of the finest modern scientific equipment, a requisite to modern biomedical research, Dr. Glaser said. Medical and graduate students will be enabled to pursue their studies in a modern and efficient setting with excellent laboratories and classrooms.

-MORE-

The four-story structure--three floors and a basement--is located between the Stanford Hospital and Medical School wings. It encompasses 152,000 gross square feet of space and includes facilities for the investigative programs being carried on by the departments of anesthesia, genetics, medicine, obstetrics, pediatrics, preventive medicine, psychiatry, radiology, and surgery.

The building is connected by corridors with all floors of the existing Center. Among the attractive features are the landscaped courtyards created by the noted architect, Edward Durell Stone, who designed the medical complex. The research building has identical architecture, including the sandstone-shaded grillwork characteristic of the entire Center.

The third floor is occupied by the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine directed by Nobel Prize winner Dr. Joshua Lederberg and dedicated to an attack on the problem of mental retardation on a broad front.

In the Kennedy Laboratories, several Medical School departments will join in bringing their particular disciplines to bear on the investigation of disease processes that bring sorrow to untold numbers of families and economic waste of immense proportions.

Also housed in the building are laboratories made possible by the National Aeronautics and Space Administration for research in the fields of space biology and biomedical instrumentation.

According to Dr. Lederberg, who coined the word "exobiology" (the study of life beyond earth), the instruments developed there will analyze, by means of unmanned spacecraft missions to other planets of the solar system, the chemical evolution of these celestial bodies, thus enlarging our vision of biology. And they will have wide application in biological, chemical, and medical research at Stanford and elsewhere."

Research in the new building covers varied areas of investigation. In the obstetrics laboratory, for example, a tiny rabbit fetus is kept alive in an artificial uterus. The fetus, attached by umbilical cord to the placenta floating above it, gets oxygen from surrounding fluid. The experiment is being carried out by Dr. Robert C. Goodlin, assistant professor of gynecology and obstetrics, to provide a better understanding of the processes of reproduction and prenativity.

The Division of Infectious Diseases has been waging war against viruses. Under the direction of Dr. Thomas C. Merigan, investigators are studying Interferon, the cell-produced antiviral agent that may prove as effective as penicillin and the other antibiotics have been against bacteria.

-MORE-

Studies of how hormones affect the maturation of the central nervous system are conducted by Dr. Seymour Levine, associate professor of psychiatry. Dr. Levine has demonstrated in rats that sex hormones, present during critical periods of development, condition the organism's central nervous system to produce permanent changes in adulthood.

In the Kennedy Laboratories, a noted biochemist from England, Dr. Eric Shooter, is conducting an extended study of proteins in the brain and red blood cells as part of the research in mental retardation.

Another investigator, Dr. Herbert Schwartz, a pediatric hematologist, is studying hemoglobin--the oxygen-carrying protein in red blood cells. The research is hoped to provide information relating to anemias and the chemistry of developing organisms, and greatly increase present knowledge of human genetics.

The Department of Anesthesia, under the direction of Dr. John Bunker, executive head and professor of anesthesia, is conducting a large-scale study of the pharmacology of anesthetics and related drugs. Knowledge of how drugs act on the body is still sketchy and more information is needed, according to Dr. Bunker.

Dr. Quentin M. Geiman, professor of preventive medicine and specialist in tropical diseases, heads a team studying human, simian and rodent malaria, a project of interest to the U.S. Army in Viet Nam.

In the field of diagnostic radiology, Dr. Herbert L. Abrams, professor of radiology and chief of the division, is conducting studies in congenital heart disease. Dr. Abrams' pioneering research has led to the development of multiplane motion picture techniques for determining the nature of heart defects and the extent to which coronary arteries are narrowed, thus increasing the danger of heart attacks.

Dr. Thomas Stamey, professor and chief of the Division of Urology, supervises studies of renal function which have added a great deal to the proper management of patients with renovascular hypertension. Dr. Stamey and his associates also have shown that cure of urinary infections is dependent upon the urinary level of the antibacterial agent, departing from the traditional approach based on serum sensitivity concentrations.

In the field of transplantation, Dr. Halsted Holman, Guggenhime professor of medicine, is working on the hypothesis that certain parts of donor cells can be used to induce tolerance of the recipient to transplanted organs. Isolation and characterization of these cell fractions is now under way and may result in an important "breakthrough" for overcoming the immunological barrier in kidney, liver, and other transplants.

Editors: The following story details some of the contributions of the Stanford medical school faculty to medicine during the School's first half century. It is included for background in connection with the dedication of the Clinical Sciences Research Building May 26.

Stanford medical researchers are responsible for major steps in the treatment of diseases.

Their contributions to advances in medicine have included fields as varied as heart surgery, heredity, viruses and vision.

Among the big names in medicine at Stanford have been Dr. Emile F. Holman, emeritus professor of surgery, who performed the first "blue baby" operation in the West 19 years ago, and the late Dr. Thomas Addis, co-developer of a simple treatment for Bright's disease, a serious kidney ailment.

Other medical pioneers at Stanford have been:

The late Dr. Paul John Hanzlik, former head of the department of pharmacology, who produced an oral drug for treating syphilis. This drug and another developed earlier at Stanford were especially effective in combating the dangerous late stages of the disease when it attacks the brain and the nervous system.

Dr. Harold K. Faber, emeritus professor of pediatrics and former head of the department, who was one of the first researchers to alert surgeons about the danger of removing tonsils during the polio season. He later demonstrated the need for a "live" vaccine to assure complete polio immunity.

Findings of the late Dr. Ernest C. Dickson, professor of medicine, led to a revolution in the canning industry. His work showed that certain foods, likely to carry the bacteria which cause deadly botulism, must be cooked longer and at higher temperatures than other foods.

Dr. Charles H. Danforth, emeritus professor of anatomy, found in the 1930's that hormones and genes do not act independently in determining heredity but are intricately interrelated. His work, together with that of others elsewhere, changed the outlook of science on heredity.

Research by the late Dr. Frank W. Weymouth, professor of physiology, led to improved methods of testing pilots' vision. The tests were used in World War II for screening pilots.

A team of Stanford researchers discovered the cause of valley fever, which made countless soldiers ill at bases in arid sections of the country in World War II. The late Dr. Emmet Rixford and Dr. William Ophuls found that an airborne fungus spore spread the disease and could be curbed by dust control. Research was continued by Dr. Charles Edward Smith, now dean of the School of Public Health at the University of California, who developed a skin test for the disease.

-MORE-

Another pioneer in medicine was the late Dr. John Kent Lewis who, with Stanford professors A. W. Hewlett and G. D. Barnett, published some of the early work on vascular sounds, exercise and respiration and was one of the first to study thyroid hormone in relation to the heart.

The late Dr. Lowell A. Rantz, professor of medicine and associate dean of the Medical School, was an authority on bacterial diseases and their treatment. During World War II, Dr. Rantz served as consultant and member of the U.S. Army Commission on Hemolytic Streptococcal Diseases and published a classical series of reports in which the relation between streptococcal infection and its complications, including rheumatic fever, was clearly demonstrated.

This impressive record of contributions in teaching, care of patients and research, established by earlier generations of Stanford Physicians, is being carried on today.

One of the leaders in research on transplantation of the heart is Dr. Norman E. Shumway, professor of surgery. He has developed many of the specific surgical techniques that are in widespread use and has been remarkably successful with heart transplantation in dogs.

Dr. Arthur Kornberg and his staff have isolated a natural catalyst that stimulates production of DNA, the complex chemical which determines heredity in animals, plants and bacteria. Using this catalyst they have produced DNA apparently like that found in nature. Such work would lead to a better understanding of heredity. For his work, Dr. Kornberg shared the Nobel Prize in medicine with Dr. Severo Ochoa of New York University in 1959.

Dr. Joshua Lederberg, one of the youngest Nobel Prize winners in recent years, did part of his award-winning work when he was 21. At Yale in 1946 he and former Stanford professor Edward L. Tatum discovered that bacteria, contrary to belief then, sometimes reproduce sexually. Dr. Lederberg also discovered "transduction", in which a virus carries a genetic fragment from one bacterium to another. Understanding of this process may lead to new findings about cancer.

Two recent contributions to the health field were made by Dr. John A. Luetscher, professor of medicine, and Dr. Judith Pool, senior research associate in medicine.

For many years, Dr. Luetscher has sought the causes of edematous states or what was known as dropsy. He has added greatly to our knowledge of disordered protein and hormone imbalances and to salt and water metabolism in the production of edema. He was the first to show that a hormonal factor, later called aldosterone, was involved in various edematous conditions.

Dr. Pool and her associates have found an encouraging treatment for hemophilia, the bleeder's disease. She has developed a simple and inexpensive way to concentrate antihemophilic globulin AHG, a protein substance lacking in the blood of hemophilia victims. Small amounts of AHG concentrate can end dangerous hemorrhages in hemophilia patients.

The achievements of these distinguished professors and scientists are highlights in a 53-year history of exceptional medical research and service at Stanford. The Medical School's outstanding reputation in the United States and abroad attracted these leaders in medicine who, in turn, have contributed to Stanford's continuing tradition of excellence.

Dr. Emmet J. Lamb, 33, assistant professor of gynecology and obstetrics at Stanford University School of Medicine, has been awarded one of ten "Macy Faculty Fellowships in Obstetrics" by the Josiah Macy Jr. Foundation of New York.

The ten grants total $450,000 for three years and are designed to meet basic salaries of young staff members and encourage their commitment to academic obstetrics. The recipients were chosen from candidates submitted by 37 medical schools.

Dr. Lamb's major fields of research are gynecologic endocrinology and infertility in women. He is presently on a year's leave of absence as a U.S. Public Health Service postdoctoral fellow at the Hormone Laboratory of the Karolinska Institute in Sweden.

After receiving his M.D. degree from Northwestern University in 1957, Dr. Lamb served his internship at Los Angeles County General Hospital and his residency at Johns Hopkins Hospital and UCLA Medical Center. He joined the Stanford faculty as an assistant professor in 1963.

Dr. Herbert E. Longenecker, president of Tulane University, and other noted speakers will highlight the dedication of the new $6 million Clinical Sciences Research Building at the Stanford University School of Medicine Thursday, May 26.

On hand also will be three eminent scientists, Dr. Leon Eisenberg, professor of child psychiatry at Johns Hopkins University School of Medicine; Dr. Seymour S. Kety, chief of the Laboratory of Clinical Science of the National Institute of Mental Health; and Dr. David H. Hubel, professor of neurophysiology at Harvard Medical School.

Among the invited guests are Mr. and Mrs. R. Sargent Shriver, executive director and executive vice president, respectively, of the Joseph P. Kennedy, Jr. Memorial Foundation, Mrs. Edward Kennedy, and other members of the Kennedy family, representatives from the National Institutes of Health and the National Aeronautics and Space Administration, members of the Stanford University Board of Trustees, faculty and university administration, alumni of the School of Medicine, and other dignitaries.

The public ceremony marking the official opening of the research building will be held at 2:30 p.m. on the lawn in front of the Medical School Building.

President Longenecker will discuss "Public and Private Partnership for Medical Progress." He will be introduced by Dr. Robert J. Glaser, vice president for medical affairs and dean of the Medical School.

Dr. Longenecker is a noted biochemist and was formerly vice president of the University of Illinois in charge of the Chicago Professional Services and dean of research in the natural sciences at the University of Pittsburgh.

Following the keynote address, Stanford University President J. E. Wallace Sterling will present the building to Richard E. Guggenhime, president of the University Board of Trustees.

An open house and tours for the public will be conducted following the dedication ceremonies.

To start off the day-long celebration, there will be a colloquium at 9:30 a.m. in Dinkelspiel Auditorium stressing the theme: "Development and Intellect." The colloquium, sponsored by the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine, will feature the following presentations:

(1) Dr. Eisenberg on "The Development of Intelligence"

(2) Dr. Kety on "Neurochemistry and Adaptive Behavior"

(3) Dr. Hubel on "Plasticity in the Immature Central Nervous System"

-MORE-

Dr. Eisenberg is an authority in the field of child psychiatry and mental deficiency and is known for his pioneering studies of the effects of drugs in psychiatric disorders of children, and the neuropsychiatric aspects of reading disability. He also has written extensively on childhood problems in relation to the family and on preventive psychiatry.

Dr. Kety is known for his research in the fields of cerebral circulation and biological psychiatry, and for at least 150 articles on his work. In 1951, he became the first scientific director of the National Institute of Mental Health and the National Institute of Neurological Diseases and Blindness. In order to resume active research he left his post in 1956 to become chief of the Laboratory of Clinical Science in the National Institute of Mental Health. From 1961 to 1962 he was Henry Phipps Professor and chairman of psychiatry at Johns Hopkins University, but then he returned to the NIH.

Dr. Hubel is known best for his contributions to the physiology of the brain, particularly the processes involved in the transformation of information in the visual system. His fundamental investigations, set out in more than 50 papers, have contributed to a better understanding of the organization of the visual system at the single neuron level.

After the presentation, Nobel Prize winner Dr. Joshua Lederberg, head of the department of genetics and director of the Kennedy Laboratories, will make the concluding remarks.

The Clinical Sciences Research Building, located between the Stanford Hospital and Medical School wings, is the first major addition to the $22 million Stanford Medical Center since it was opened seven years ago. It was financed in part by the University's PACE Program (Plan of Action for a Challenging Era) and government grants.

These include gifts of $1 million each from the Rockefeller and Joseph P. Kennedy, Jr. foundations, a Health Research Facilities grant of more than $2 million from the National Institutes of Health, a grant of more than $500,000 from the National Aeronautics and Space Administration, and contributions from other private sources.

The four-story structure -- three floors and a basement -- covers 152,000 gross square feet of space and contains facilities for the departments of Anesthesia, Genetics, Medicine, Obstetrics, Pediatrics, Preventive Medicine, Psychiatry, Radiology, and Surgery. It also includes the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine which are dedicated to an attack on the problem of mental retardation on a broad front of scientific research.

Also housed in the building are facilities supported by NASA for research in the fields of space biology and biomedical instrumentation.

-MORE-

The new building was planned as part of the Medical Center, but funds were inadequate to finance it when construction began in the Center in 1957.

"The completion of the new building represents the result of a vigorous and continuing effort on the part of President Sterling, members of the Board of Trustees and the medical faculty -- an effort directed toward better health for mankind," Dr. Glaser commented.

"The concept of medical education at Stanford has included three major ideas: that medical students ought to be near other university departments so that they can be exposed to all fields of knowledge as they pursue the study of medicine; that, as a consequence, they will learn to treat 'not the disease but the man'; and that physicians must remain students of medicine all their lives if they are to give their best to society.

"The Clinical Sciences Research Building will facilitate research in such fields as cancer, heart disease, and mental retardation, research that heretofore has been carried on at Stanford under extremely cramped conditions. But it will be more than a birthplace for discovery; it will also provide a setting wherein the student, working side by side with seasoned scientists, will acquire the inductive investigatory techniques he will utilize throughout his professional career, be he family physician, specialist or research scientist."

FOR PM RELEASE FRIDAY, MAY 13, 1966

Dr. Keith B. Taylor, a specialist in diseases of the gastrointestinal tract, has been named the George de Forest Barnett Professor of Medicine at Stanford University School of Medicine.

Announcement of the new professorship was made today by Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine, at the annual Stanford medical alumni-faculty reunion on the University campus.

Dr. Taylor is currently an associate professor of medicine and head of the Division of Gastrointestinal Medicine. He also is chief of gastrointestinal medicine of the Stanford medical staff at the Palo Alto-Stanford Hospital Center.

"The George de Forest Barnett Professorship honors a physician famed for his interest in both patients and students as human beings," Dr. Glaser commented. "Dr. Barnett was chief of the Stanford Medical Service at the San Francisco City and County Hospital for 25 years. Everyone recognized in him the presence of a great man and his opinion was respected without question. He loved the students; he knew them all well and discussed their problems in a practical and helpful way.

"As a teacher he was outstanding. The course in physical diagnosis was one of his particular interests and under his guidance it became widely recognized as outstanding."

Primarily responsible for the creation of the Barnett Professorship are members of the Stanford Medical Alumni Association who established the Barnett Memorial Fund in 1955 shortly after Dr. Barnett's death at the age of 71.

The University Board of Trustees has stipulated that the Barnett Professor should have "the highest possible competence as a stimulating teacher and advisor of students."

-MORE-

"Dr. Taylor exemplifies in every way the emphasis at Stanford on the fact that medicine is both science and art, and that the latter requires the insight and compassion gained from a broad and deep cultural background," Dr. Glaser said.

Dr. Taylor has been a member of the Stanford medical school faculty since 1962. He was born in London, England, and holds degrees in physiology, biochemistry, and medicine from Oxford University. From 1954 to 1959 he was lecturer in medicine at Oxford University, and from 1959 to 1960 a visiting professor at the University of Chicago under a Rockefeller Travelling Fellowship.

Among his honors are the Radcliffe Prizes in Medicine and Pathology from Oxford University. Dr. Taylor is a member of several professional societies including the British Medical Research Society, American Gastroenterological Association, American Society for Clinical Investigation, and the British Society of Immunology.

Dr. and Mrs. Taylor and their five children live at 530 Melville in Palo Alto.

Dr. Barnett's widow, Dr. Anna F. Barnett, was graduated from Stanford University School of Medicine in 1924 and is an emeritus member of the clinical faculty. She resides on the Stanford campus. Dr. and Mrs. Barnett's daughter, the former Margaret Barnett, is also a graduate of the Stanford Medical School and is married to Dr. F. Eugene Yates, associate professor and acting executive head of the Department of Physiology.

Richard H. Lanzerotti and William G. Hayden, third year medical students, shared top honors for "The Outstanding Student Research Paper" at the sixth annual Medical Student Day held recently at Stanford University School of Medicine.

The two students split the $150 award presented each year by the Palo Alto Medical Clinic.

Lanzerotti's paper concerned immunization studies on mice, and Hayden's paper described research on the mechanism of disturbed heart rhythm known as atrial flutter. Seven other students presented papers based on their own research.

All participants were selected by a student-faculty committee, and papers were judged by Dr. Stanley Schrier, associate professor of medicine; Dr. LeRoy Pesch, associate dean and professor of medicine; Dr. Sidney Raffel, professor and executive head of the department of medical microbiology; Dr. Marcus A. Krupp, Palo Alto Medical Clinic, and Dr. Leland Blanchard, Stanford Medical Alumni Association.

Dr. Leo Eloesser, Stanford University's 20-year emeritus professor of surgery and tireless worker on world health projects, will be the featured speaker at Stanford's annual Medical Alumni-Faculty Reunion.

The Reunion will be held Friday, May 13, from 9:30 a.m. to 4:30 p.m. in Dinkelspiel Auditorium on campus.

Dr. Eloesser, now living in Tacambaro, Mexico, will speak on "Some Early American Chest Surgery."

The 85-year-old surgeon was a United Nations medical consultant from 1951 to 1953 and is well known for his humanitarian missions to Russia, Spain, South America and China before and during World War II. He was a member of the Stanford faculty from 1913 to 1946.

Dr. Herbert N. Hultgren, associate professor of medicine and head of the division of cardiology, will also address the conference. He will discuss "Lessons from High Altitude," based on his studies and medical observations in the Peruvian Andes. He is a 1943 graduate of the Stanford University School of Medicine.

Following the two speeches, the School of Medicine will host an informal luncheon for returning alumni and members of the faculty in the south courtyard of the new Clinical Sciences Research Building.

The annual Alpha Omega Alpha Lecture sponsored by the Stanford chapter of the AOA honorary medical society will highlight the afternoon program.

Dr. Belding H. Scribner, professor of medicine and head of the division of nephrology at the University of Washington School of Medicine, will speak on "The Conservative and Definitive Treatment of Chronic Uremia." Dr. Scribner is a 1945 graduate of the Stanford School of Medicine.

The program will conclude with a dinner-dance for all alumni and faculty at the Villa Hotel in San Mateo. The classes of 1916, 1921, 1926, 1931, 1936, 1941, 1946, 1951, 1956 and 1961 will be celebrating special reunions.

The Stanford Alumni Conferences for all Stanford graduates are being held on campus the following day, Saturday, May 14.

A new series of public lectures featuring outstanding leaders in the field of mental retardation will be presented by the Stanford University School of Medicine.

Dr. Joshua Lederberg, Nobel Prize winning geneticist and head of the department of genetics at the Medical School, will inaugurate the series titled "Progress in Mental Retardation" Wednesday (May 4) at 8 p.m. in Room M106 of the Medical School Building.

He will speak on the subject of "How Intellectual Performance is Distributed."

The five weekly lectures are being presented in conjunction with the forthcoming dedication of the new $6 million Clinical Sciences Research Building at Stanford Medical Center, May 26. The new building houses the Lt. Joseph P. Kennedy, Jr., Laboratories for Molecular Medicine which are directed by Dr. Lederberg.

The Laboratories, made possible by a $1,100,000 gift from the Joseph P. Kennedy, Jr., Memorial Foundation, are dedicated to an attack on the problem of mental retardation on a broad front of scientific and medical research.

Many disciplines are represented in the research program including biochemistry, genetics, pediatrics, obstetrics, neurology and psychiatry.

"Mental retardation is one of the most compelling challenges to the humanitarian and social instincts of medicine," says Dr. Lederberg. "It is also one of the most provocative challenges to investigative insight and experimentation across a broad frontier of scientific studies. It concerns the development of the most complex of biological functions, the most highly evolved organ of the body--the human brain."

The dates, topics, and lecturers who will take part in the presentation of this series are:

May 11, "The Developing Brain." Dr. Frank Morrell, professor and head of the division of neurology, Stanford University School of Medicine.

May 18, "Abnormalities of the Developing Brain: Mechanisms and Therapy." Dr. Guy M. McKhann, associate professor of pediatrics and medicine; Lt. Joseph P. Kennedy, Jr., senior research scholar in mental retardation, Stanford University School of Medicine.

May 25, "Sources of Failure in Intellectual Function as Demonstrated by the Problem of Reading Disability." Dr. Leon Eisenberg, professor of child psychiatry, Johns Hopkins University School of Medicine, Baltimore, Md.

June 1, "Genes, Chromosomes and Mental Retardation." Dr. Luigi Luzzatti, associate professor of pediatrics and preventive medicine, Stanford University School of Medicine.

All of the lectures will be presented at 8 p.m. in Room M106 of the Medical School Building.

The popular notion that exercise leads to longer and healthier life was assailed today by two Stanford Medical School specialists in rehabilitation.

Dr. Jose C. Montero, assistant professor of medicine, and Dr. Kenneth D. Smythe, a postdoctoral fellow in rehabilitation medicine, said that experts disagree on what physical activity can do besides making people tired.

"The term 'physical fitness' is now being bandied about by politicians, physicians and physical cultists as if it were the universal panacea," Drs. Montero and Smythe reported. "Lack of uniformity in the definition of terms, the different backgrounds and ambitions of the investigators, and the biases associated with this vital subject leave most of us more confused than enlightened."

Their conclusions appear in the June issue of the Journal for Physical and Mental Rehabilitation.

Drs. Montero and Smythe are unhappy with the present definition of fitness which considers only the person's physical ability to function. They believe that any good yardstick for measuring fitness should take into account other factors including environmental and cultural demands of the society.

"If we accept the definition of fitness as the ability to function comfortably in a specific environment," the physicians argued, "fitness becomes not a goal in itself, but rather an expression of anatomic, metabolic, and physiologic readiness to perform a task."

"The man in the gray flannel suit," they wrote, "is physically fit to stalk the asphalt jungle if he can imbibe three martinis before lunch and dance the Watusi with his client's wife. The primitive jungle dweller, on the other hand, stalks his prey with a cunning that depends more on a strong, well-coordinated body than a strong stomach. Yet each is considered physically fit to perform in his environment."

Obviously, a criterion of fitness for an individual cannot be ascertained without relating to his vocational, avocational, and cultural demands, Drs. Montero and Smythe said. Yet we measure stamina by assigning numerical values to physical factors--endurance, strength, coordination, and cardiovascular and metabolic states.

"Even if we carefully evaluate those factors," the physicians said, "there is still one more variable which must be analyzed before a true measurement of fitness can be made. Motivation, the will to perform, is the most powerful stimulant to purposeful activity known to man."

-MORE-

While it is difficult to measure motivation, some facts are known, they said. For instance, some severely mentally ill patients are so lacking in their will to perform, yet their potential for normal physical activity may be completely unchanged. On the other hand, there have been frail individuals performing great feats of strength or endurance under severe stress.

The Stanford physicians cited the story of a fragile, middle-aged woman who lifted a 2000-pound car to free her son who was pinned under it as a dramatic example of human motivation.

Viewing fitness from the environmental standpoint has important implications for the treatment of disabled persons, Drs. Montero and Smythe believe.

When disease or accidents cause loss of fitness, there are two ways of attacking the problem. "We can either change the environment so that the loss is no longer significant or we can help the individual compensate for his loss so that he can function again in the same environment," they said. The latter can be accomplished by retraining of which the human body is capable.

Drs. Montero and Smythe said that while volumes have been written on the beneficial effects of activity and exercise, nobody seems to agree on the type and amount of activity that are necessary for the maintenance of health. Their findings from a scan of the literature show that:

* There is no conclusive evidence that physical activity contributes to longevity.

* Exercise does not prevent disease. (Persons involved in physically demanding activities visit the doctor as often as their more sedentary counterparts and the Russians have not escaped the Asian flu despite an all-out effort to improve physical fitness.)

* While exercise improves the collateral circulation of the heart and enhances recovery from surgical conditions, the amount of improvement is not always related to the intensity of the exercise. (Preliminary studies at Crystal Springs Rehabilitation Center in San Mateo, California, show some patients respond favorably to short periods of exercise while others with the same impairment need a more intensive program to achieve similar results.)

The physicians concluded that maintenance and improvement of fitness need serious study involving the fields of medicine, physiology, physical education, and the behavioral sciences.

To be simply enamored with one or another type of physical exercise is dangerous as well as misleading, they noted.

"The secret of establishing a warm, empathetic relation with an adolescent is to listen to him."

This common-sense advice to colleagues and parents alike appears in a new booklet "The Physician and the Adolescent," by Dr. Richard D. Cutter, Palo Alto pediatrician for almost 25 years.

Published posthumously by the Peninsula Volunteers, a charitable organization, the booklet reflects Dr. Cutter's pioneering views on the responsibility of the physician to the adolescent. It comprises a series of memoranda originally circulated to colleagues at the Palo Alto Medical Clinic.

"Most young people who come to a physician," Dr. Cutter wrote, "have been surfeited with fatherly advice. Parents, school authorities and youth counsellors have, in effect, repeatedly told him: 'You don't need to waste time telling me your side of your problem; just follow my good advice.' As soon as the adolescent realizes that his doctor is going to listen, the physician has got it made."

Dr. Cutter wrote the first of his 13 memoranda in November 1961, and the last in August 1964. He suffered his fatal heart attack on August 13, 1964 at the age of 55.

The publication of his papers was made possible through donations to the memorial fund of The Peninsula Volunteers, Inc., in which Dr. and Mrs. Cutter were active members.

The Peninsula Volunteers recently presented copies of the booklet and an $800 check to Dr. Robert H. Alway, professor and acting head of the department of pediatrics at Stanford University School of Medicine. Dr. Cutter was a member of the clinical faculty and an alumnus of the medical school.

The booklets will be placed in the Mary K. and Harold K. Faber Pediatric Library, a portion of which has been dedicated to Dr. Cutter, and the check will be used to purchase books on adolescent pediatrics.

Dr. Faber, emeritus professor of pediatrics at Stanford, and Mrs. Faber attended the informal ceremony. Dr. Cutter was one of Dr. Faber's students. Also present was Dr. Cutter's daughter and son-in-law, Mr. and Mrs. William Parker of San Francisco.

Mrs. Paul Reinhardt of Palo Alto, editor of the booklet, wrote in the introduction: "The personal loss to his boys and girls and to their parents, and to his many friends and colleagues, can never be replaced, but it is the hope of the Peninsula Volunteers that publication of these papers will illuminate and perpetuate his ideas."

Dr. Cutter's ideas covered a wide range of subjects from "How to Trap the Adolescent and Charm Him" to "The Problem of the Innocent Young Doctor vs. the Hip Adolescent."

-MORE-

Here are a few excerpts from the booklet:

On Adolescence: "Of the many definitions of adolescence, I prefer this one: the emergence from childhood to maturity. Like all emergences, whether of molten lava from the volcano or of a strip-teaser from her clothing, adolescence is made up of explosive and dramatic episodes."

On Growth: "This subject is of great concern to adolescents in the United States where the boys all want to be tall Texans and the girls all want to be petite, dainty and fragile (like a steel trap). Elsewhere, of course, things are different: in Russia, I understand, a girl isn't desirable unless she has the physique of a tractor mechanic; and in Italy I know for a fact that no youngster worries about stature (because they all know they'll be short)."

On Sex: "Parents keep asking their physicians to give their pubescent children 'a good fatherly talk' about sex. There's no such thing and even if there were, the youngsters probably wouldn't listen to it. But there are several good books and pamphlets that can be made casually available for the interested adolescent to read."

On "All That Jazz": "Very important to the adolescent who digs. And if the twist, frug, swim remain popular, they may solve the problem of lack of exercise which is at the bottom of so many adolescent obesity cases."

On the New Pediatrics: "The excitement of unravelling the complexities of family relations as one's contact with a family broadens from year to year; the challenge of dealing with parental concern about eating habits, bowel habits, too-tall daughters, too-short sons; the development of empathy with a rebellious adolescent; the sustaining of parental faith in their difficult children: all these facets of the New Pediatrics are, to an old pediatrician, the greatest things that have happened during a generation of practice."

On Advice to Parents: "The next time the adolescent in your home suddenly pulls the roof down on top of you, don't panic; remember your own youth. Judge and discipline him by adult standards if you must, but understand him by the standards of his--and your--adolescence. As they say today: He may not always dig, but he's hip."

On Advice to Physicians: "Keep faith with your adolescent patients, don't despair, hope for the best, and remember that Rome wasn't built in a day."

On Adolescent Problems: "The so-called problems of adolescence are nothing more than what should be expected to happen to any rapidly growing, active, cerebrating, self-propelled organism."

Copies of "The Physician and the Adolescent" are available on request at Little House, 800 Middle Avenue, Menlo Park.

Palo Alto-Stanford Hospital Center and Foothill College will graduate the country's first academically trained inhalation therapists next Sunday, June 19.

Nine students have completed the joint hospital-college program established last year to train students in the care of patients who have difficulty breathing. They will receive certificates at the Foothill College graduation ceremonies.

The new program is the only one of its kind in the United States and has been fully approved by the American Medical Association. Other training programs in inhalation therapy are primarily hospital oriented.

In the joint program, Foothill offers general education and related science courses, and the Hospital Center provides supervised clinical experience.

Among the general courses are effective writing and speaking, American government and psychology. The scientific curriculum includes anatomy, physiology, physics and microbiology.

The clinical experience concentrates on the application of inhalation therapy procedures to emergency, obstetric, pediatric and surgical patients.

Six of the nine graduates will begin advanced training in inhalation therapy at the Palo Alto-Stanford Hospital Center. Another first of its kind, the Hospital Center's new postgraduate program will allow the student to specialize for one year in a particular area of inhalation therapy such as respiratory and cardiac emergencies, pulmonary function, or rehabilitation of chronic lung diseased patients.

Three graduates have accepted positions at other hospitals: two in California and one in Oregon.

The students' names and addresses are listed below:

ATHERTON - Marilyn Hoeffer, 85 Loyola Ave.
EAST PALO ALTO - Roberta E. Simmons, 2017 Clarke Ave.
MENLO PARK - Erika Furedi, 816 Arnold Way
- Collis Harris, 1103 Hollyburne Ave.
MONTA VISTA - David Knight, 10181 Lowe Ave.
MOUNTAIN VIEW - Douglas Bennett, 2200 California St., #6
- Thomas S. Bowman, 1870 Ednamary Way, #A
- Sandra Dunkle, 2762 Doverton Sq.
PALO ALTO - Pat Breach, 3129 Alma St.

The American Heart Association has presented Dr. Stanford Kroopf, Palo Alto physician, a bronze medal for distinguished service in the field of coronary care units and cardiac resuscitation.

He is the first cardiologist to receive the Heart Association's bronze medal in this field. The award was presented at the annual California Heart Association meeting in Los Angeles.

Dr. Kroopf was chairman of the committee which recommended and initiated the installation of a coronary care unit at the Palo Alto-Stanford Hospital Center. Construction of the Hospital Center's four-bed unit began this month.

Dr. Kroopf is a member of the Hospital Center's Palo Alto medical staff and clinical assistant professor of medicine at Stanford University School of Medicine. He lives at 87 Coghlan Lane, Atherton.

FOR RELEASE AFTER 11 A.M., SATURDAY, JUNE 11

Editors: Names of students receiving M.D. degrees in your area will be included in a story mailed from Stanford University on June 10. Home addresses of award winners are listed on page 2.

Stanford University School of Medicine presented awards to six graduating students at the class convocation Saturday, June 11, in the courtyard of the new Clinical Sciences Research Building.

Degrees will be awarded June 12 to 45 men and nine women, members of the third class to complete Stanford's five-year medical curriculum. The five-year program was inaugurated when the school moved from San Francisco to the Stanford campus in 1959.

One degree will be awarded posthumously to Lucien Kabat, a 27-year-old senior who died of lung cancer late last month. Kabat had completed all requirements for his M.D. and would have received the degree with his class on Sunday.

At the convocation, the Harold K. Faber Pediatric Award of $200 was presented to Michael Charles Klein. This award is given to potential contributors to child health in recognition of accomplishments in pediatrics.

Robert Alan Marcus received the $500 Borden Undergraduate Research Award in Medicine, given by The Borden Company Foundation, Inc. to a senior student for research "meritorious in his class."

Gerald Rosen was presented the $250 National Foundation Merit Award for "outstanding research in the area of birth defects," and Laurence Joseph Sloss won the $200 Upjohn Achievement Award for outstanding clinical performance. The Dr. and Mrs. Joseph Fife Surgery Award of $500 was given to John Bordy.

-MORE-

James Thomas Pappas was awarded the first Stanford Medical Alumni Association Scholarship of $400. The alumni scholarship was presented in recognition of high scholastic achievement and leadership.

Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine, welcomed the guests, and Dr. LeRoy A. Pesch, associate dean, presented the awards. Dr. Harold K. Faber, emeritus professor of pediatrics, announced the recipient of the award named in his honor.

Class president Irwin Jacobs presented the annual Arthur L. Bloomfield Award for excellence in the teaching of clinical medicine to Dr. Cleve B. Baker, instructor in dermatology.

Dr. Robert A. Chase, professor and executive head of the Department of Surgery, delivered the faculty address, and Dr. Glaser administered the Hippocratic Oath.

Students and their parents' names and addresses are listed below:

CALIF., LOS ANGELES - Robert Alan Marcus, Dr. & Mrs. Simson Marcus, 740 N. Kings Rd.

N.J., WANAQUE - Michael Charles Klein, Mr. & Mrs. Philip Klein, 24 Dale Rd.

N.Y., JAMAICA - Gerald Rosen, Mr. & Mrs. Nathan Rosen, 82-05 189th St.

ILL., RIVER FOREST - James Thomas Pappas, Mr. & Mrs. Thomas Constantine Pappas, 1306 Franklin Ave.

GLENCOE - Laurence Joseph Sloss, Prof. & Mrs. Laurence Sloss, 123 Euclid Ave.

ROMANIA - John Bordy, Mr. & Mrs. Joseph Bordy.

Dr. Edward Siegel has been appointed associate professor of radiology at Stanford University School of Medicine and radiation safety officer for the Palo Alto-Stanford Hospital Center.

In addition to teaching radiologic physics, Dr. Siegel will be associated with Dr. Joseph Kriss, director of the Division of Nuclear Medicine, in the development of techniques for the clinical application of radioisotopes.

As radiation safety officer, he will direct the Hospital Center's expanded safety program designed to protect patients and personnel from radiation hazards. He will have supervisory and advisory responsibility for all safety aspects involved in the Hospital's use of radioactive materials and radiation-producing machinery.

Dr. Siegel also plans to continue his research on cultured human cells to determine the mechanisms responsible for actions produced by hormones.

Before coming to the Stanford Medical Center, Dr. Siegel was a U.S. Public Health Service Special Fellow in cellular biophysics at the University of California at Berkeley. From 1948 to 1962, he was in charge of the Medical Physics Laboratory at Montefiore Hospital in New York.

He received his B.S. degree from the College of the City of New York and his Ph.D. in biophysics from the University of California at Berkeley.

Dr. Siegel and his wife recently moved from Berkeley to Portola Valley.

Dr. Morgan Berthrong, director of laboratories at Penrose Hospital in Colorado Springs, has been appointed visiting professor and acting head of the department of pathology at Stanford University School of Medicine.

His additional appointment as acting pathologist-in-chief at the Palo Alto-Stanford Hospital Center was approved Wednesday night (July 27) at the monthly meeting of the Hospital Board of Directors.

Dr. Berthrong will assume his responsibilities September 1 and serve through June 30, 1967.

He succeeds Dr. Kenneth Weinbren who has returned to his teaching post at the Postgraduate Medical School of the University of London. Dr. Weinbren was acting head of the department of pathology and acting pathologist-in-chief for the 1965-66 academic year.

Dr. Berthrong has been a member of the staff at Penrose Hospital and on the faculty of the University of Colorado School of Medicine since 1954. Before becoming director of laboratories at Penrose, he was professor and chairman of the medical school's department of pathology from 1959 to 1961. He is presently a clinical professor of pathology.

He received his M.D. degree from Harvard University in 1943 and interned at Roosevelt Hospital in New York City. From 1946 to 1953 he was a resident physician and faculty member at Johns Hopkins Hospital and Medical School.

Dr. and Mrs. Berthrong are bringing their four youngest of six children to spend the year with them at Stanford.

Editors: Photographs are available on request.

When Dr. Radha Pant returns to India next month she is prepared to tackle two of her country's biggest problems--malnutrition and economic depression.

With the assistance of the South Palo Alto Lions Club, Stanford University School of Medicine and the Palo Alto Medical Research Foundation, Dr. Pant is taking home $15,000 worth of surplus equipment to continue her research on the nutritive value of beans and the output of silk worms.

Dr. Pant is a research associate at Stanford on a year's leave of absence from the University of Allahabad. She began collecting supplies two months ago, when the Indian government offered to exempt its scientists from paying customs duty on professional and scientific equipment acquired abroad.

Several medical school departments and the Palo Alto Medical Research Foundation have given her materials and instruments ranging from chemicals to a large machine for measuring tissue respiration. She has purchased many additional items herself.

The South Palo Alto Lions Club donated $1,000 to cover shipment costs.

Dr. Pant came to Stanford last September to study the biochemistry of insects under Dr. Raymond B. Clayton, associate professor of biochemistry. She plans to extend this work to Indian silk worms, hoping to improve both the quality and quantity of silk produced.

Her primary concern, however, is the biological and nutritive value of beans and peas, traditional staples of the Indian diet.

India, she notes, is one of the world's largest producers of legumes, but many varieties grow wild and are inedible because of their unpleasant odor and toxic properties.

Dr. Pant intends to isolate protein from the waste legumes and incorporate it into the human diet. Her experiments may mark a significant breakthrough in the country's attempt to fight malnutrition.

-MORE-

"Most of the people in India suffer from protein deficiency," she explains. "They are either vegetarian by religious preference or tend toward vegetarianism because meat is expensive and vegetables are more readily available."

Dr. Pant's research reflects the determination and ability she has demonstrated throughout her life. After receiving her Ph.D. in biochemistry from the University of Bombay, she began a 20-year teaching career at the University of Allahabad, where she is an assistant professor and head of the division of biochemistry.

Her great desire is to see the biochemistry division established as an autonomous department rather than an adjunct to the department of chemistry, as it is now.

Before leaving for the United States, Dr. Pant visited India's President Sarvapalli Radhakrishnan, whom she has known since childhood, and asked him if he would help her establish a separate department. This month she received notice that a department of biochemistry has been included in India's next five-year plan and is scheduled to open in 1967.

Among the people of India eagerly awaiting Dr. Pant's return are her husband, a professor of botany at the University of Allahabad, and their three children--two daughters 17 and 12, and a son 15.

Two years ago Ruth Bell of Sacramento was making medical history.

Today she swims if she feels like it and zips off from her home in West Sacramento to a downtown hospital where she works as a medical records secretary.

But in doing that she is still making medical history.

Mrs. Bell, a 24-year-old divorcee, was the subject of a pioneering operation at Palo Alto-Stanford Hospital Center in which she received a healthy kidney transplanted to her body from her mother, Mrs. Wilma Davis.

It was an important accomplishment for Stanford University surgeons who had long wondered how to overcome the human body's tendency to reject tissue not its own.

On the doctors' report Mrs. Bell's disease was listed as chronic kidney failure.

In her own memory the trouble came on slowly, a feeling of increasing tiredness beginning when she was 17.

Doctors made the diagnosis but kept Ruth going with drugs and a series of diets aimed at keeping a proper balance in her blood chemistry.

At one point, her menus consisted of fruit and rice and various liquids. Now she can eat what she pleases.

In July 1964 her kidneys failed, and her mother volunteered as a donor. "We knew kidney transplant surgery was experimental, and many of our friends tried to discourage us," her mother said. "But we had no choice. Now we are glad our decision was right."

Mrs. Bell was the first human patient at Palo Alto-Stanford Hospital Center on whom a new technique, previously tested successfully on dogs, was used.

The method, devised by a Stanford surgical research team, permits doctors to administer safely the powerful drugs that help prevent the body's natural antagonism to foreign tissue.

"The method is not a radical new approach," the team says, "but rather a more precise use of existing techniques."

-MORE-

The key is the ability to predict rejection by measuring the kidney blood supply after transplantation. A fall in blood flow is the first detectable signal that the rejection mechanism is cranking up. When such a warning is flashed, the doctors inject drugs to suppress the threatened rejection by restoring blood flow.

Since Mrs. Bell's transplant, six such operations have been performed between relatives at Palo Alto-Stanford Hospital Center. An eighth transplant was performed between twin brothers seven years ago. All patients today lead normal lives.

It will be two years ago on July 31 that Mrs. Bell went home from the hospital. Physicians regard a two-year survival as something of a record, for only about 30 percent of all the kidney transplant patients are known to have lived that long.

Those who survive during the first two critical years may live for five or more, the physicians said, adding that in the meantime new and better drugs may become available and new knowledge developed about the immunity reaction.

Now back in Sacramento, Ruth works, takes care of her six-year-old daughter Kathryn, attends business school, and is active in the Mormon church.

Next month she will be taken off immuno-suppressive drugs which had the tendency to make her overweight.

"The doctors are crossing their fingers with me," she says, "I am their first experiment."

As to her own life, Ruth evaluates it as "completely normal."

#####

Editors: Mrs. Bell's home address is 913 Poplar Street, West Sacramento. She is employed by the Arcade General Hospital in Sacramento.

(Mailed July 18, 1966)

SHE IS A MEDICAL PIONEER--Miss Ruth Bell of Sacramento who underwent a kidney transplant operation at Stanford Medical Center in 1964 today leads a normal life. Physicians regard a two-year survival as a record for only 30 percent of such patients live that long. With new drugs and better techniques of monitoring the body's natural tendency to reject foreign tissue, physicians expect Mrs. Bell to do equally well in the future.

Palo Alto, California

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos (321-5310)

Stanford Medical School physicians searching for new methods of treatment for patients with acute respiratory problems have just received a three-year grant of $248,000 to continue their painstaking effort.

The grant to a team of anesthesiologists headed by Dr. John P. Bunker, professor and head of the Department of Anesthesia, comes from the John A. Hartford Foundation, Inc. of New York. It brings to more than half a million dollars the amount that Stanford has received from the foundation for research in the management of acute disturbances in respiration since 1963.

In a progress report on the research, Dr. Bunker said that scientists are finally beginning to understand some of the causes and the course of respiratory complications that follow disease, accidents, and surgery.

There are three general areas of investigation:

* Respiratory problems resulting from mechanical limitations of breathing--due to surgery of the upper abdomen, chest injuries, and such diseases as polio, tetanus, and myasthenia gravis.

* The effect of drugs and certain metabolic diseases on the brain's respiratory center.

* The course of infections that is a frequent complication of low-level lung ventilation --and the question whether the microorganisms are the patient's own or from other sources.

Dr. Grant Fletcher, assistant professor of anesthesia, is in direct charge of the program in the intensive care ward of the Palo Alto-Stanford Hospital Center where the clinical research is being conducted. The third member of the team is Dr. J. Weldon Bellville, professor of anesthesia, who is directing the research into the role of drugs and disease in the nervous system's control of breathing.

The research has been focused on respiratory problems caused by surgery of the upper abdomen. Concerned here chiefly, Dr. Fletcher explained, are operations in such areas as the stomach, gallbladder, the pancreas and the small bowel.

He added that this sort of surgery--particularly when performed on males--is notoriously associated with a high frequency of lung collapse.

He quoted studies showing that 50 percent of such surgical patients, if given no preventive treatment for pulmonary complications, will develop at least a minor degree of lung collapse. This disorder--revealed on X-ray films as areas of collapse throughout the lungs--is usually completely reversible if found early and causes no apparent lasting harm although it may delay recovery from surgery for several days.

-MORE-

This type of lung collapse, Dr. Fletcher said, is always potentially dangerous as the possible forerunner of pneumonia and even cardiac arrest and death. Postsurgical pain so far seems to be the most obvious cause of the condition although there may be other mechanisms or chemical changes involved.

"Typically, the postsurgical patient with pain is likely not to breathe deeply for fear of enhancing his pain," Dr. Fletcher said. "It would seem to be this shallow breathing that leads to atelectasis (lung collapse)."

The research team studied two methods of treating the condition--breathing treatments using a respirator, and pulmonary physiotherapy. Both treatments require about 20 minutes and are applied every four hours during the first two postsurgical days, the team reported.

The physiotherapist works with patients before surgery, teaching them the mechanics and value of proper breathing. After surgery she instructs patients how to position themselves in bed and how to hold themselves so that pain is reduced to a minimum when they cough or breathe deeply--or how to transfer the strain of breathing to other muscles.

Respirator treatment and physical therapy were given to two groups of selected patients after surgery. A third group received the normal type of nursing care. None of the patients had a previous history of lung disease.

"The patients who received respirator treatment and the patients who received physical therapy did not develop significant recognizable lung collapse," Dr. Fletcher said. "The patients who were given normal nursing care developed lung complications to the extent of 50 percent."

Drs. Bunker and Fletcher agreed that preventive treatments not only cut the incidence of lung collapse but also cut the length and cost of postoperative care.

To detect early very small degrees of lung collapse, not visible in routine X-rays, the investigators utilized a new method of analyzing blood for oxygen content. The method makes use of a small analyzer at the patient's bedside and measures blood oxygen in the patient's artery.

The research team also has completed studies of the performance of respirators--machines used to help patients who cannot breathe on their own.

"Patients," Dr. Fletcher said, "often require the support of these machines for weeks or months and it is important to know how each machine will work with the various degrees and types of lung ailment. The new studies have provided us with a much better basis for choosing the right respirator for the right patient."

Future studies will investigate the degree to which different methods of artificial respiration reduce a patient's breathing effort and need for oxygen.

The group will also study the sources of infection that so often lead to pneumonia in patients with breathing difficulties. The investigators are interested in checking their suspicion, based on earlier work, that faulty breathing creates an internal environment in which bacteria inside the body can cause disease.

"Meanwhile," they said, "we have learned how a few simple steps can affect a real improvement in hospital-born infections, especially the importance of using disposable sterile gloves and suction catheters."

Dr. Henry S. Kaplan, professor and executive head of the department of radiology at Stanford University School of Medicine, has been elected president of the American Association for Cancer Research, a scientific society with more than 1,000 members throughout North and South America.

Dr. Kaplan was elected president at the Association's annual meeting held recently in Denver, Colorado. He has been an active member since 1945, serving on the board of directors, as chairman of the program committee and vice president.

The group meets once a year to exchange information on new developments in cancer research and publishes the monthly journal Cancer Research. Membership is composed of scientists who have contributed original and significant research in a variety of biomedical fields.

Dr. Kaplan is well known for his research on Hodgkin's disease and was a leading figure in the design and use of Stanford's linear accelerator "cancer gun." He is presently continuing work with high-energy radiation treatment of cancer.

FOR PM RELEASE SEPTEMBER 5, 1966

Editors: Story for p.m.'s September 5, coincides with publication of report in the Journal of the American Medical Association.

A special committee of the National Academy of Sciences-National Research Council today reported that halothane, implicated several years ago in rare cases of liver damage among surgical patients, is one of the safest anesthetics in general use.

The report, published in the current issue of the Journal of the American Medical Association, resulted from a four-year intensive national study of halothane in which the Stanford University School of Medicine played a key role.

The study was based on information from 856,000 patients who had surgery under general anesthesia in 34 hospitals from 1959 to 1962. Among institutions which took part were Peter Bent Brigham, the Mayo Clinic, and hospitals associated with the universities of Michigan, Miami, California, Iowa, Columbia, Duke, and UCLA.

According to the report, one-third of the patients studied had been given halothane, the rest other commonly used anesthetics. There were only nine cases of unexplained liver damage among these patients, but halothane could not be ruled out as a possible cause.

The main conclusions of the report are:

* Fatal liver damage following anesthesia and surgery is rare.

* Halothane, rather than being a dangerous anesthetic is as safe as or safer than other general anesthetics. Its safety is reflected in an overall mortality of 1.87 percent compared to an average for all anesthetic practices of 1.93 percent.

* There is no evidence to support the manufacturer's warning of halothane being dangerous to patients with known liver or gallbladder disease.

In the study, participating hospitals were required to report postoperative deaths that occurred in the hospital within six weeks of general anesthesia, and to abstract case records, categorizing them by the type of anesthetic used.

To provide information on the general population of patients from which the deaths were reported, each hospital was required to report the number of general anesthetics administered, categorized by types of anesthetics. All deaths suspected to have been caused by liver damage were reviewed by a panel of pathologists with a special interest in liver diseases.

-MORE-

During the four-year period of study, approximately three-quarters of a million anesthetics were given to patients in the 34 participating hospitals. There were 16,840 deaths of various causes, and in 60.4 percent of these an autopsy was performed with particular attention to the abdomen.

The case history of each patient, including the type of anesthetic he received, and similar information on all the cases that were brought under scrutiny, was punched on data processing cards and forwarded to the computer center at Stanford University, where Dr. John P. Bunker, professor of anesthesia and chairman for the national halothane study, and Dr. William H. Forrest, Jr., assistant professor of anesthesia and coordinator of the study, directed the research. The computer compared each type of operation in an effort to detect any significant difference between patients receiving halothane and those receiving other anesthetics.

Other Stanford faculty members who participated in the study were Dr. Lincoln E. Moses, professor of statistics, and Drs. Ellis N. Cohen and J. Weldon Bellville, professors of anesthesia.

"One of the most important findings of the study is that we have no systematic methods for appraising new therapeutic techniques," Dr. Bunker commented in an interview.

"It is doubtful whether any drug was ever more extensively studied both before and after its introduction than halothane," he said. Prior to the national halothane study, halothane had been given to patients perhaps 10 million times, yet it was impossible to give firm, reliable answers to many basic questions about its effects."

Dr. Bunker explained that many drugs are being withdrawn or labeled "dangerous" by the Food and Drug Administration simply on the basis of poorly designed studies and insufficient clinical evidence.

To remedy the situation, the halothane study committee has recommended "the establishment of a cooperating group of institutions to serve as a panel-laboratory for the acquisition of trustworthy information on new drugs as they come into use."

Dr. Philip R. Lee, assistant secretary for health and scientific affairs in the Department of Health, Education and Welfare, will give the keynote address at a Stanford University convocation on community health resources August 31 and September 1.

Dr. Lee, member of a famed Palo Alto medical family, will speak on "Health Programs for the Poor". His address is scheduled for 2:30 p.m. Thursday.

The two-day program will be held in Dinkelspiel Auditorium and is open to the public. Community leaders, educators and professionals in the health science field across the country have been invited to attend.

The convocation is the concluding event of a 10-week Student Health Project sponsored by the University of Southern California School of Medicine and supported by a demonstration grant from the Office of Economic Opportunity.

Under this project, 90 students of nursing, medicine, dentistry and social work have spent the summer studying community health problems in poverty areas of nine California counties. They have worked in county hospitals and health departments, in the offices of private physicians, and with community action programs such as Project Head-Start.

The students are from 40 health science institutions in 11 states. About half are from schools in California, including Stanford, the University of California, and the University of Southern California. At the convocation they will present papers on their findings, experiences and recommendations.

Stanford President J.E. Wallace Sterling and U.S.C. President Norman H. Topping are honorary chairmen of the event. Faculty co-chairmen are Dr. Roger O. Egeberg, dean of the U.S.C. School of Medicine, and Dr. Robert J. Glaser, vice president for medical affairs and dean of the Stanford School of Medicine.

-more-

Appearing on the program are Dr. Paul F. Wehrle, faculty co-director of the project and chairman of the departments of pediatrics and communicable diseases at U.S.C.; Michael R. McGarvey, student co-director of the project and fourth year medical student at U.S.C.; Paul C. Ward, state administrator for health and welfare, and Dr. Paul F. O'Rourke, special assistant to the Governor of California for anti-poverty planning and director of the California Office of Economic Opportunity.

Other participants include Dr. Leopold J. Snyder, chairman of the California Medical Association Rural Health Committee; Dr. R. Bruce Jessup, coordinator of the anti-poverty program for the California State Department of Public Health, Edna J. Brandt, chief of the Bureau of Nursing for the California State Department of Public Health, and Dr. Max Schoen, dental surgeon in Los Angeles.

Spyros G. Andreopoulos, 36, has been appointed information officer at Stanford University School of Medicine, and editor of Stanford M.D., the magazine of the Stanford Medical Alumni Association.

The appointment was announced by Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine.

Andreopoulos succeeds Samuel Moffat who resigned in August to devote full time to freelance writing.

Andreopoulos has been with Stanford since 1963. Before coming to Palo Alto, he was assistant director of information services at The Menninger Foundation in Topeka, Kansas, and editor of The Menninger Quarterly for nearly six years.

Prior to that he was associate editorial page editor for the Wichita (Kan.) Beacon, a writer with the United States Information Agency in Greece, and public information officer in Japan. He came to the United States from his native Greece in 1952 as a Fellow of the Institute of International Education. He became a U.S. citizen in 1959.

He obtained his B.A. from Wichita State University, and took the course in science writing at Northwestern University under the auspices of the National Science Foundation. He is a member of the National Association of Science Writers.

Andreopoulos, his wife, and daughter live at 882 Southampton Drive, Palo Alto.

A $7.50 increase in standard room rates was approved Tuesday night at a special meeting of the Palo Alto-Stanford Hospital Center board of directors.

New room rates starting immediately are $42.50 for ward beds, $47.50 for semi-private rooms, and $54.50 for private rooms.

Robert Klein, president of the hospital board, said the board hopes that the higher room rates would provide the necessary income to support the new salary scale agreed to by the hospital and the nurses Sunday, and to finance other wage increases.

Under the new agreement, 407 nurses will receive a 21.5 percent pay raise on top of a five percent increase they received last July.

In addition, the hospital board decided to increase salaries of other hospital personnel most of whom will receive 5 to 15 percent increases. These pay raises to other employees have been granted to maintain salary scales at realistic levels.

The cost of the new salary package is estimated at $1.3 million, a 13 percent increase in total hospital payroll.

The increased cost for nursing pay raises is 60 percent of the total pay increases. The remaining cost is for pay increases of non-nursing personnel and retroactive evening and night shift differentials.

Editors: Story was transmitted by phone Aug. 14, 1966.

An agreement was reached Sunday night between the Palo Alto-Stanford Hospital Center and the 340 nurses who had threatened to resign over a salary dispute.

The new agreement, termed "unique" by both sides, sets a salary range of $481 to $782 a month maximum which can be reached after continued service of five years. The latter feature, according to the administration and the nurses, is to encourage career nurses for service at the bedside.

The nurses originally asked for a starting salary of $613 a month, and 15 and 17 percent differentials for evening and night shift work.

The new scale also provides 10 and 12 percent differentials for evening and night shift work and an annual bonus of 10 percent of one month's salary for nurses who have reached their maximum salary scale.

The starting salary of $481 is for nurses who have graduated from 2-year junior college programs. If they have previous experience it will count toward a higher starting salary, according to the agreement. The salary scale for diploma nurses is $530 to $676 a month, with a possible maximum of $782.

The nurses agreed that the salary scales will be effective for 13 months (August 8, 1966 through August 31, 1967), an arrangement unique among San Francisco and East Bay hospitals which have interim salary agreements with their nurses to December, 1966, subject to possible retroactive increases by fact-finding.

Meanwhile, the Hospital has lifted emergency measures taken during the week to reduce its occupancy and began to admit patients as usual.

PALO ALTO - STANFORD HOSPITAL CENTER

STAFF NURSE SALARY SCHEDULE

Staff Nurses are paid according to their experience, educational preparation, and ability. There are six groups into which they may be hired - depending upon their qualifications. Or, they may be promoted into succeeding groups as they progress professionally, through acquiring further experience, education, and proficiency.

	Range	Salary	A.A. Degree	Diploma	B.S. Degree	M.S. Degree
A.A. Degree	33	481-505	0-12 mos.exp.			
Staff I	35	530-676	12-18 mos.exp.	0-6 mos.exp.		
Staff II	36	556-710	18-24 mos.exp.	6-12 mos.exp.	0- 6 mos.exp.	
Staff III	37	584-745	24-36 mos.exp.	12-24 mos.exp.	6-12 mos.exp.	
Staff IV	38	613-782	36 mos.exp.	24 mos.exp.	12-24 mos.exp.	
Staff V (Clinical Associate)						
*Staff VI (Nurse Clinician)						

Each staff nurse is evaluated periodically to determine her eligibility for advancement into the succeeding groups. Advancement is a personal thing and dependent entirely upon the nurse and what she produces and brings as an individual to her position.

*Staff Nurse VI position is not currently open.

Dr. Eugene M. Farber, professor and executive head of the department of dermatology at Stanford University School of Medicine, has been elected president of the Society for Investigative Dermatology, an international organization of scientists involved in skin research.

Dr. Farber was elected president at the society's annual meeting held recently in Chicago. He has been an active member since 1948, serving on the program committee and as vice president.

The society is composed of more than 1,000 members who exchange information on new developments in dermatologic research and publish the Journal of Investigative Dermatology.

For many years Dr. Farber and his associates have been engaged in extensive studies on psoriasis, a skin disease characterized by the formation of scaly red patches on the surfaces of the body.

An old, rejected theory, which explains why the heart beats irregularly in certain heart disorders, and its proponents have been fully exonerated by a Stanford University physician.

New evidence, published in the current issue of the Annals of Internal Medicine, the journal of the American College of Physicians, is likely to revise present thinking about the heart and cause medical textbooks to be rewritten, according to the author, Dr. David Rytand, Bloomfield professor of medicine at Stanford University School of Medicine.

In an interview, Dr. Rytand said the evidence demonstrates beyond doubt the validity of the circus movement theory, formulated by clinical physiologist Sir Thomas Lewis in England almost half a century ago.

The circus movement theory sought to explain the mechanism of one of the most common heart irregularities, atrial fibrillation--and the less common but related one, flutter.

This condition refers to a quivering of the heart muscles that through disease have fallen out of their rhythmic action. A heart that beats in abnormal rhythm cannot pump blood properly to the blood vessels, and the result leads to disability in varying degrees, if the condition is left untreated.

It was Dr. Lewis' contention that the electricity which arises in the region of the upper heart chambers (atria) and regulates the heart beat was entrapped in a ring-like pathway around the great veins. The same impulse went around and around and made the atrial tissue flutter, a condition that sometimes precedes a full-blown fibrillation.

In the normal heart, the electric charge which causes muscles to contract spreads throughout the atrial tissue somewhat like a ripple from a pebble dropped in a still pond. Once it has done its job, the impulse fades out and a new one is generated.

The theory was discredited in the United States, Dr. Rytand contends, because doctors have simply misunderstood Dr. Lewis' hypothesis or overlooked the clinical evidence.

"Those who did study the theory and found the experimental evidence unsatisfactory were trapped by an optical illusion which caused them to misread their patient's electrocardiograms," Dr. Rytand said.

Twenty years before Dr. Lewis published his papers on the circus movement theory, Dr. Alfred G. Mayer, a physicist and marine biologist, demonstrated the existence of circus movement in the jellyfish.

-MORE-

"If we cut off the marginal sense-organs of the scyphomedusa Cassiopea, the disk becomes paralyzed and does not pulsate in sea-water," Dr. Mayer wrote. "The disk will pulsate in sea-water, however, if we make either a single ring or a series of concentric broken-ring like cuts through the muscular tissue of the sub-umbrella. Then upon momentarily stimulating the disk in any manner, it suddenly springs into rapid, rhythmical pulsation so regular and sustained as to recall the movement of clock work."

Today most medical textbooks deny that there is a circus movement. A recent book, THE HEART, edited by Drs. J. Willis Hurst and R. Bruce Logue, says "there is no experimental evidence to date" in support of the circus movement theory.

The most accepted explanation suggests that irregular atrial action results from the inability of tissue to respond to a rapid rate of stimulation arising in a tiny, abnormally active region of atrial tissue.

But Dr. Rytand disagrees with this notion. After repeating the jellyfish and other animal experiments himself to confirm that they showed circus movement, he reviewed the evidence for and against the theory on both American and foreign journals.

He found experiments that have clearly shown the existence of an entrapped circuit wave in rings of living heart and other tissue cut from a variety of animals including mammals, in purely atrial rings, and also in inert iron wire and electronic computers.

"The favorable evidence was all there," he said, "but nobody was really looking at it. The evidence against Sir Thomas Lewis' point of view was very poor."

Dr. Rytand's previous belief in the circus movement was further supported by his own clinical observations on 40 patients, beginning with two cases in 1952. Both were women who had flutter at unusually slow atrial rates. Flutter which is closely related to fibrillation is a highly regular abnormal mechanism, and therefore lends itself to analysis, Dr. Rytand explained. He cautioned, however, that this type of flutter can only be detected in the electrocardiogram. It has nothing to do with the heart "flutter" many of us experience from time to time.

The atrial rate in the two patients ranged from 180 to 200 compared to the usual 300 cycles per minute. In both patients, Dr. Rytand noticed, the upper heart chambers were huge, one due to a congenital defect, the other due to a narrowing of the tricuspid valve.

He concluded that the slow rate was evidence of circus movement. "The electrical impulse in the atrial area had a long way to travel around. Longer cycles meant a slower rate per minute," he said.

The reason many investigators have failed to find satisfactory evidence in support of the circus movement can be traced not only to a misunderstanding of the theory, but also to an optical illusion in the electrocardiogram (EKG), Dr. Rytand believes.

In flutter each passage of the entrapped electricity around the great veins shows up in the EKG as a line with a downward slope. When the atrial rate is slow the angle of this slope is often reduced to such an extent that it resembles the flat line of paroxysmal atrial tachycardia, another heart irregularity not caused by circus movement.

Dr. Rytand and his colleagues discovered that the true appearance of this line can be restored by the use of a cylindrical lens to permit accurate reading of the EKG.

The same lens placed on the EKG enabled Dr. Rytand to observe circus movement on a patient's heart during open heart surgery, the first time this was ever accomplished, in 1961.

Dr. Rytand noted that although the circus movement has been rejected, ignored, and misunderstood, physicians had found a treatment for flutter by electroshock. Such a shock discharges the heart of its electricity and disrupts the ring-like circuit. It is only an irony of history that the understanding of the condition comes half a century later to aid in a better diagnosis of this heart abnormality.

####

(Mailed Aug. 10, 1966)

Dr. David Rytand, Bloomfield professor of medicine at Stanford University School of Medicine, uses wire on heart model to demonstrate how circus movement theory works. Instead of spreading throughout the atrial tissue to cause muscles to contract, electricity which regulates heart beat is entrapped in a ring-like pathway around the great veins, causing muscle to flutter.

A prominent Spanish physician who underwent open heart surgery at the Palo Alto-Stanford Hospital Center is glad he took the advice of a friend, even though he had to travel over 4,400 miles to Palo Alto, Calif.

Dr. Antonio Cantos will return to his home in Seville, Spain next week after a successful heart valve operation at the hospital.

"A colleague at the University of Seville Medical Center insisted I come here for the operation, so I came, and I'm thankful," said Dr. Cantos, a practicing gynecologist and obstetrician.

The friend and colleague is Dr. Ramiro Rivera, a heart surgeon in Seville. Dr. Rivera was a postdoctoral fellow at Stanford University School of Medicine during the 1964-65 academic year. He studied under Dr. Norman E. Shumway, professor of surgery, who performed the delicate operation on Dr. Cantos.

Dr. Cantos, 46, had a calcified aortic valve. The aortic valve lies at the juncture of the heart's main pumping chamber and the aorta, the body's main trunk artery. Calcium deposits prevented the valve from functioning properly. The calcified valve was replaced with an artificial valve in a four-hour operation July 22.

Dr. Shumway has performed 500 aortic valve replacements at the Palo Alto-Stanford Hospital Center since March 1963.

Dr. Cantos was dismissed from the Hospital Center August 3 and will remain in the area about 15 days, until he is strong enough to travel. Then Dr. and Mrs. Cantos will fly directly home. Four children are awaiting their return, including a baby boy who was only two weeks old when they left.

Dr. and Mrs. Cantos are staying with Mr. and Mrs. Alexandre Drosdoff in Menlo Park, also the home of Dr. Rivera when he was at Stanford.

A $10,000 gift to the Stanford University School of Medicine for research in urology has been announced by the Norwich-Eaton Foundation, Norwich, New York.

The gift will make it possible to equip a laboratory for research in the treatment of urinary tract infections, one of the commonest bacterial infections in man.

The laboratory will be located in the newly dedicated Clinical Sciences Research Building. Investigations will be under the direction of Dr. Thomas Stamey, professor and head of the Division of Urology, and Dr. Duncan Govan, associate professor of surgery.

One of the problems which will be studied in the new laboratory concerns the effectiveness of drugs in the treatment of urinary tract infections, Dr. Stamey said. Another relates to finding out where bacterial infections come from. Once the infections can be localized then physicians can work at eliminating their recurrence and hopefully even preventing them entirely.

Many of the infectious bacteria are "normal" in human intestines, Dr. Stamey explained, but these tiny germs frequently invade the urinary tract, especially the bladder, where they multiply rapidly and sometimes lead to severe kidney ailments--kidney stones, kidney failure and even death.

"It is also apparent that the major problem in urinary tract infections is one of reinfection rather than failure to cure specific infections," Dr. Stamey said.

He added that urinary tract infections are 14 times more common in women than men suggesting that the cause of infection or reinfection may lie in the female anatomy. Studies across the country show that at least one percent of elementary school girls are afflicted with some form of urinary tract infection.

Stanford University today made a formal offer of an estimated $5 million to purchase the City's interest in the Palo Alto-Stanford Hospital and said it would make additional land available contiguous to the Herbert Hoover Pavilion for expansion of a community hospital.

The proposal was contained in a letter to Mrs. Frances Dias, mayor of Palo Alto, from President J. E. Wallace Sterling.

It called on the City to join in negotiations with University representatives that would lead to a change in the present joint hospital ownership.

In response to a request by the City, the University last January indicated its interest in acquiring Palo Alto's ownership in the Hospital. University representatives have appeared before the finance committee of the City Council to outline the basis of Stanford's letter and the committee asked the University to make a specific offer.

"Accordingly, the University has carried forward its studies," President Sterling wrote, "and I am now authorized by the Board of Trustees to transmit to the City of Palo Alto a definitive proposal: The University is prepared to pay the City a sum of money equivalent to the fair market value of the City's share in the building and equipment of the Palo Alto-Stanford Hospital in order to acquire such share.

"Based on a very preliminary analysis, we estimate this sum to be of the order of $5 million; as soon as we have that figure refined, we shall inform you of it."

Palo Alto's original investment in the buildings and equipment of the joint Hospital was approximately $4.2 million.

Dr. Sterling added that if the City accepts the University's offer and joins in terminating the lease of land presently adjoining the Hospital Center, "the University will make available on equivalent terms additional land contiguous to the Hoover Pavilion for expansion of a hospital facility on that site."

An analysis made by an experienced hospital architect, employed as a consultant by the University, has shown that the Hoover Pavilion, with additional land at the site, can be expanded into an outstanding hospital that will serve the community well.

"If the City elects not to accept the University's offer," Dr. Sterling said, "Stanford will plan for the expansion of its own hospital facilities, and will in due course create the Stanford University Hospital as an independent unit, both administratively and functionally."

-MORE-

In any event, Dr. Sterling said, both parties will be faced with "the necessity of reconsidering the legal agreements relating to the Hospital."

"We have always recognized," Dr. Sterling said, "that until additional beds are available in the community, no change in the present organization of the Palo Alto-Stanford Hospital can be made. Inasmuch as it will be some years until new construction can be completed, we believe that there is urgent need for an early decision."

Last January Stanford, acting on a request dated May 10, 1965 by the City, announced that it was interested in acquiring the City's share in the 437-bed Hospital. The decision was based on a report prepared by the Stanford Medical School administration and faculty, headed by Dr. Robert J. Glaser, vice president for medical affairs and dean of the medical school.

The faculty report stated that Stanford must have a University Hospital with 450 to 500 beds and the usual supporting facilities such as operating rooms and laboratories to support its major effort in medical education, patient care, and research.

The report noted that if the University did acquire the Hospital, members of the volunteer faculty, many of whom also serve on the Palo Alto medical staff, would continue to have access to the University's facility for hospitalization of patients from the community.

A citizens' committee previously had recommended to the Council "to determine through contact with Stanford University officials, the potential interest of the University in leasing the Palo Alto Pavilion and Core portion of the Palo Alto-Stanford Hospital to accommodate the expanding needs of the Stanford Medical School."

The citizens' committee report also stated that "as part of the negotiations with Stanford, (the City) obtain the release of the old Palo Alto Hospital facility (Hoover Pavilion) from the joint ownership agreement between the City and the University and conclude a new agreement concerning the old hospital site which would allow potential expansion ... under City auspices."

Thirty-two students from Ravenswood High School are seeking answers to the question "What is Life?" in the third summer science program sponsored by Stanford University School of Medicine.

The students are exploring highlights of modern experimental biology and medicine in an intensive six weeks of lectures, discussions, films, field trips and laboratory work.

Dr. Leonard A. Herzenberg, associate professor of genetics and director of the program, describes the medical school project as an attempt to broaden the students' awareness of the opportunities and challenges in science by exposing them to the university environment.

"We hope to provide sufficient incentive, guidance and help to enable these students to prepare and qualify for college," he said.

Three medical students, Edward Bernstein, Michael Volen and Dieter Eckert, organized details of this year's curriculum and are working with the high school group as teaching assistants and counselors. Assisting them is Harvey Cole, a science teacher at Ravenswood.

The teaching staff consists of more than 60 faculty members from the medical school's clinical and research departments, as well as biologists from Stanford, San Francisco State and the University of California at Santa Cruz.

The program, which is supported by the National Science Foundation, began July 5 and will continue through August 12. Activities are centered in the medical school's Max C. Fleischmann Laboratories which are designed and equipped for medical student teaching.

During the first few weeks, the students traced the evolution of man and surveyed the behavioral sciences. This included a laboratory study of one-celled organisms, a film on child birth, and discussions on genetic and environmental aspects of intelligence, the effect of drugs on behavior, and sleep and dreaming.

They have examined the tide pools at Hopkins Marine Station in Monterey, toured the California Academy of Sciences in San Francisco, visited patients at the Veterans Administration Hospital, and observed the children at Stanford Children's Convalescent Hospital.

-MORE-

Before the program is over, the young scientists will study some of the problems of tissue transplantation and perform their own experiments with skin grafting on mice. They will also collect and culture bacteria and isolate DNA, the chemical basis of life.

Despite their busy schedule, the students have plenty of free time for discussing and evaluating their experiences. They all agree that they like the program, especially the medical school atmosphere.

"It's not at all like high school," one girl explained, "you really feel like a medical student; we're treated with respect and our opinions are important."

Several students cited the discussions on psychiatry as being particularly helpful in giving them a better understanding of human problems which they can relate to their own high school experiences.

Others mentioned the opportunity to meet professors and medical students. "We have the chance to work with people we'd never know otherwise," commented one boy.

Dr. Herzenberg and his staff hope the students will continue their association with the medical school at the end of the six-week program. For the past two years, a number of students have been hired as laboratory assistants, a few have arranged tutorial programs with individual medical or graduate students, and some have requested faculty assistance in initiating laboratory experiments during the school year.

"Many of our young alumni are going to top colleges and universities," Dr. Herzenberg added, "including Reed, the University of California, the University of Santa Clara and Stanford."

Stephen M. Baird of Glendale, Calif., has received a $1,575 tuition scholarship for one year at Stanford University School of Medicine from the Los Angeles County Medical Association. The award was announced by Dr. Joseph P. O'Connor, president of the board of directors of the medical association.

Baird is a 1966 graduate of Stanford University. He earned his A.B. degree in biology and was on the dean's list his sophomore, junior and senior years. He is a member of Alpha Tau Omicron fraternity and has served as a representative to Stanford's student legislature.

Last summer he worked at the U.C.L.A. Medical School in the laboratory of Dr. E. R. Arquilla, conducting research on the immunological properties of insulin. This experience, he says, helped him decide to go into medicine. He is particularly interested in neurophysiology and the behavioral sciences.

In addition to the tuition scholarship from the medical association, Baird received an $800 university scholarship to cover the cost of books, a microscope and supplies.

He is the son of Mrs. Lois M. Baird of 565 W. Stocker, Glendale, and Kenneth K. Baird of 2553 N. Lincoln, Burbank.

Dr. David E. Rogers, prominent educator and investigator in the area of infectious diseases, will give the third John Kent Lewis Memorial Lecture at Stanford University School of Medicine October 4.

He will speak on the "Clinical Spectrum of Histoplasmosis in Man" at 5 p.m. in Room M106. Histoplasmosis is a fungal disease affecting the liver, lungs and spleen. It produces chronic infection similar to certain forms of valley fever or tuberculosis.

Dr. Rogers is professor of medicine and chairman of the department of medicine at Vanderbilt University School of Medicine in Nashville, Tenn. He also serves as physician-in-chief at Vanderbilt University Hospital.

He is well known for his studies of staphylococcus, an organism which has become more resistant to antibiotic action in the last few years and produces the disease commonly referred to as staph infection.

Dr. Rogers was born in New York City, the son of the distinguished psychologist, Professor Carl R. Rogers. He obtained his undergraduate education at Ohio State University and graduated from Cornell University Medical College in 1948.

After completing his medical internship and residency at Johns Hopkins Hospital, Dr. Rogers served two years as an officer in the Naval Medical Corps. In 1954 he returned to Cornell as assistant professor of medicine and visiting investigator at the Rockefeller Institute for Medical Research. He joined the Vanderbilt faculty in 1959.

Dr. Rogers is the author of more than 75 papers, the majority dealing with infectious disease. He is a member of the United States Public Health Service advisory committee on influenza research and the committee on microbiology of the National Academy of Sciences-National Research Council.

In addition to his professional activities, he has been active in civic affairs and has served on the Tennessee State Advisory Committee of the United States Commission on Civil Rights. In 1961 he was designated one of the ten outstanding young men in the United States by the United States Junior Chamber of Commerce.

The annual lecture is dedicated to the memory of Dr. John Kent Lewis who died in 1961. Dr. Lewis was professor of medicine and chief of the Stanford Medical Service at San Francisco General Hospital. With Stanford professors A. W. Hewlett and George D. Barnett, he published some of the early work on vascular sounds, exercise and respiration.

Dr. R. Morton Manson of Los Gatos has been named area chairman for the 1966 annual fund for the Stanford University School of Medicine.

With research grants, tuition and student fees meeting part of its operating budget, the Stanford Medical School must count on endowment earnings and private gifts for a significant share of its operating costs. The solicitation for the School is part of the Stanford Annual Fund, started 30 years ago to help provide such support.

This year the Stanford Annual Fund seeks to raise $1.4 million in unrestricted gifts to the University, including Medical School support.

Stanford medical alumni will be solicited personally in South Santa Clara County during the six-week campaign which begins Thursday (September 29).

Dr. Manson is a graduate of Stanford Medical School of the Class of 1945. He is assistant director of medical institutions at Santa Clara County and a clinical assistant professor of medicine at Stanford University School of Medicine. Dr. Manson is married to the former Margaret Roberts, a Stanford alumna. They have two children.

FOR IMMEDIATE RELEASE

STANFORD - Few states can match California in the "glaring discrepancy" between the medically rich and the medically poor--but none are doing more to close this gap, Assistant Secretary Philip R. Lee of the U.S. Department of Health, Education and Welfare indicated Thursday (SEPT. 1) at Stanford.

A Palo Alto physician and Stanford graduate, Dr. Lee said: "It is a tragedy--for which all of us must share in the responsibility--that the lives of millions of the poor could be improved quickly and dramatically without a single major addition to our knowledge of the science and practice of medicine. The barriers here have been barriers in delivery of services, in organization, in communications, in utilization."

In the future, he added, "We must have doctors who recognize that the high child mortality rate of a community can be just as ominous as the high temperature of a single child--that the squalor and frustration of a slum area can be just as dangerous as the constant tension in the pressure-ridden executive--that the continuous presence of poverty can be just as lethal to a community as the continuous presence of a clump of malignant cells."

While Palo Alto has "perhaps the best medical care in the world," he said "We should know that the poor...in Watts, in King City, in Hunters Point, in East Palo Alto--have more than their share of chronic disease, mental illness, mental retardation, orthopedic impairments, as well as other preventable and correctable conditions."

On the positive side, he praised the California Legislature, physicians and others for passage of the so-called Casey Bill, which provides slightly more than $500 million annually in medical assistance to the poor. He said this new act "will make possible what will probably be the most extensive and highest quality medical care ever made available to the poor and to public assistance beneficiaries in the United States."

He also praised "the recent interest in medical schools in developing community medicine" and this summer's Student Health Project for creating broader awareness and action in meeting the medical problems of impoverished families.

His audience included about 90 medical, dental, nursing, and social work students who worked with the project.

It is funded by a $204,000 demonstration grant from the Office of Economic Opportunity to the University of Southern California School of Medicine.

"The Search for Animal Models of Human Disease" will be the subject of the next public lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

Dr. Keith F. Killam, associate professor of pharmacology, will speak Wednesday (Nov. 2) at 8 p.m. in Room M106 of the Medical School Building.

Dr. Killam will describe a new animal model for human epilepsy, the Papio papio baboon from Senegal. He studied the animal while on sabbatical leave last year at the Institute of Neurophysiology and Psychophysiology in Marseille, France.

The Senegal baboon, Dr. Killam says, is the first animal to possess neurological symptoms similar to those of a human disease. The baboon's response to flashing light closely resembles a human epileptic seizure.

Dr. Killam believes studies of the baboon will increase man's understanding of seizure activity and lead to further investigation of the genetic transmission of epilepsy.

"From the pharmacological standpoint," he adds, "the development of new drugs effective in treating and controlling epilepsy should be forthcoming."

Dr. Killam is a consultant to President Johnson's Advisory Commission on Narcotic and Drug Abuse and a member of the computer research study section of the National Institutes of Health. He also is a member of the research advisory committee of the State Department of Mental Hygiene.

He received his B.S. and M.S. degrees at Tufts College and his Ph.D. from the University of Illinois. He has been on the Stanford faculty since 1959.

A serious bottleneck in the development of programs to improve diagnosis and treatment of heart disease, cancer and stroke is the acute shortage of competent radiologists, a Stanford University physician warned today.

Dr. Herbert L. Abrams, professor and chief of the division of diagnostic radiology at Stanford University School of Medicine, said the day has passed when we could agree with the statement that one finger in the throat makes a good diagnostician.

"The demand for complicated medical diagnostic service has increased radically during the past decade, and continues to accelerate," Dr. Abrams said. "The national shortage of radiologists can only become more profound unless the immediate problems of strengthening academic radiology are approached with vigor and intelligence."

He cited figures showing that there are now about 7,000 radiologists in the United States and that 20,000 will be required by 1965. Five hundred are being trained yearly, with an overall loss of about 200 through death and retirement. Present training programs may be expected to produce only half of the radiologists needed by 1975.

Dr. Abrams expressed his views in an article in the current issue of the Journal of Medical Education, a publication of the Association of American Medical Colleges.

He said the diseases covered under the heart, cancer and stroke legislation will require a new breed of specialists in diagnostic radiology, trained in new techniques which have been made available only in recent years.

Radiology has made great gains recently in finding organic pathology, or disease, in the internal soft and fleshy tissues of the body, areas ordinarily invisible to x-rays, Dr. Abrams explained. There are new devices such as the TV-linked x-ray fluoroscope, and new techniques such as the passing of a plastic tube into arteries called catheterization.

Substances which are opaque to x-rays, can be placed into many parts of the body so as to reveal their outlines and shapes. Injected into a patient's aorta, the substances outline the network of arteries in the neck and shoulders and lead to the diagnosis of the cause and site of blocked circulation.

Some of the softest tissues in the body, the gastro-intestinal system, can produce the vaguest discomforts, sharpest pains, and most severe illnesses. Many of these can be seen via x-ray, thanks to barium preparations. A swallowed glass of chilled and slightly sweetened "barium cocktail" will lend its opacity to every indentation of the gastrointestinal tract.

-MORE-

The making of x-ray pictures of blood vessels, an area in which Dr. Abrams has pioneered at Stanford, has revolutionized radiology, and even the brain, one of the body's organs most invisible to x-rays, can be seen on angiograms. Arteries that have been shoved aside by growths, huge clots suffered during injury, and ballooned, burst or pinched arteries and veins can now be seen with the help of opaque solutions.

In a new form of angiography, called lymphangiography, opaque iodine compounds are seeped into the lymphatic system. Since some cancers may send their seeds through the lymph vessels, x-ray pictures of the lymphatic system can show whether an existing cancer has spread or not and, if so, where and to what extent.

"With medicare, many of the old people who could not afford involved radiologic examinations will have them more or less totally funded," Dr. Abrams said. "In the cancer patients, the number of procedures will almost certainly be far higher than in the younger segments of the population. Here, too, vessel disease abounds and vascular radiologic procedures will multiply.

"The heart, cancer and stroke centers, as they develop, can do no better than the quality of their radiologic diagnosis. They may well push facilities and personnel available for cerebral arteriography, angiocardiography, etc., far beyond their capacity."

How can the shortage of radiologists be alleviated? Medical students, Dr. Abrams suggested, "should be exposed early in the curriculum, and consistently throughout their years of medicine, to an intellectually advanced and stimulating faculty in radiology, participating in anatomy, physiology, pharmacology, pathology, and every segment of the clinical years."

The development of strong academic departments in radiology will require a new look at the organizational framework. "Ideally, diagnosis should be organized in the following subdivisions of radiology: cardiovascular, gastrointestinal, pediatric, neuroradiology, etc.," Dr. Abrams said.

"The proper objective should be balance," he said. "Some individuals may be involved in teaching and patient care for the bulk of the time. Some may be committed purely to research. The majority will participate equally in teaching, research, and patient care."

Dr. Abrams emphasized that a searching look at values is required. "The department must have strong university support and there should be a vast investment in teaching, over and above the 50 conference hours per week which are commonplace for any active university department of radiology," he said.

"The calendar of radiology has moved more slowly than the times; it must be brought up to date," he added.

A new school of medical technology opened this fall at the Palo Alto-Stanford Hospital Center. The school has a "pilot" class of three carefully selected college graduates with backgrounds in biology and chemistry.

The program consists of 12 months of lectures and practical training focused on clinical biochemistry, hematology, bacteriology and blood banking. Instruction is conducted on a full-time, 40 hours per week basis.

The students are learning to perform the basic blood, urine and tissue tests required by physicians for the diagnosis and treatment of patients. They also are trained to take electrocardiograms and to operate equipment used in pulmonary function and radioisotope studies.

The school was organized by the Department of Clinical Laboratories to help meet the current nationwide demand for medical technologists and training programs. It is supervised by Miss Kay Stevens, a Stanford graduate and medical technologist for six years.

The teaching staff includes five members of the Stanford medical school faculty, and students are encouraged to attend supplementary lectures and seminars offered by the medical school.

The new school has been approved by the State Department of Public Health and the American Society of Clinical Pathologists, a branch of the American Medical Association. This means the students will be eligible for state licensure and ASCP certification upon completion of the course.

The hospital plans to enlarge its program to include 12 students next year. Applicants must be graduates of an approved college or university and have completed certain science and math requirements.

Students in this year's "pilot" class are:

CHARLES BLANKENSHIP, 3227 Stockton Place, Palo Alto
VIRGINIA MAROVICH, 555 St. Claire Dr., Palo Alto
SUSAN WALLIS, 1376 Sierra, San Jose

FOR AM RELEASE MONDAY OCTOBER 24, 1966

An opportunity to spend a year in Venezuela, an exotic nut tree, and the search for a drug against cancer--all of these combined to produce a unique laboratory detective story involving a Stanford University pharmacologist.

The story was described today by Dr. Lewis Aronow, associate professor of pharmacology at Stanford University School of Medicine, at the 9th International Cancer Congress in Tokyo, Japan.

Dr. Aronow's account did not tell of "breakthroughs" or "cures." It rather exposed an aspect of scientific life that is little known to the public: how scientific discoveries are made.

It all began in 1964 when Dr. Aronow arrived in Caracas to spend a year as a visiting professor at the Jose Vargas School of Medicine. Among items of local lore he picked up shortly after his arrival, one particularly caught his attention. It had to do with a tree called the Coco de Mono, or monkey nut tree.

The Coco de Mono bears a delicious nut, very much like a Brazil nut. Unfortunately, nuts from some of the trees are poisonous, and can cause violent nausea and vomiting, Dr. Aronow said. Occasionally someone dies after eating them. Those who survive are miserable enough without the most prominent and humiliating symptom of all--complete, if temporary, hair loss.

It was this symptom that Dr. Aronow particularly noted. There aren't many substances which make people lose their hair, he said. Of the handful that do, most are anticancer drugs. Hair loss occurs because the hair follicles are rapidly metabolizing cells, just like cancer cells. He reasoned that the Coco de Mono poison, whatever it was, might make a good candidate for a drug against cancer.

The Stanford pharmacologist set up his laboratory in Caracas and, working with Venezuelan colleagues, particularly Dr. Francisco Kerdel-Vegas, a dermatologist who first alerted him to Coco de Mono, he prepared various extracts from the nuts. He discovered that the water soluble portion contained a potent cell poison. Using standard chemical techniques he isolated a nearly pure form of the poison, which could be crystallized.

(This work was first reported in an article in the journal Nature in 1965 and Drs. Aronow and Kerdel-Vegas were awarded a gold medal and a cash prize by the Venezuelan Society of Dermatology, Venereology, and Leprology for their discovery.)

-MORE-

A group of chemists at Wyeth Laboratories identified the cell-destroying chemical as a selenium-containing amino acid, seleno-cystathionine, which turned out to have been previously isolated from poisonous weeds and cattle forage in parts of the western United States.

When Dr. Aronow returned to Stanford from Venezuela, he began to study the compound's effects on animal cells and its possible use as an anticancer drug. He found that an ordinary sulfur-containing amino acid, cystine, was an effective antidote for seleno-cystathionine poisoning. He also showed that cystine prevented the chemical's toxic action by inhibiting a certain enzyme which was necessary to convert the selenium-containing amino acid into an active form.

This work, Dr. Aronow explained, demonstrated that the compound is toxic only to those cells or organs that have this particular enzyme. If one could find some tumor specimens with this kind of enzyme activity, then the selenium-containing substance might be a useful drug for this type of tumor.

"Our results so far show that only liver tissue has high amounts of the enzyme and no tumors," Dr. Aronow reported. "Thus the material is highly toxic to the liver, and will in all likelihood not be a useful anticancer drug."

Still, Dr. Aronow regards the work as highly successful in spite of having shed no light on the sinister secrets of cancer. "It has increased our basic understanding of the role of the two elements, sulfur and selenium, in animal metabolism," he said.

In addition, the study has certain implications for Venezuelans. Cystine can be used as an antidote in cases of accidental poisoning and might be useful in livestock diseases due to selenium-containing compounds.

Dr. Aronow's story is an example of how scientific research works. The way to great discoveries is opened by many part answers to processes which man only partially understands.

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos (321-5310)

A powerful computer to help physicians and basic scientists cope with the explosively growing body of medical knowledge will be installed at the Stanford University School of Medicine.

The new project, whose applications will range from data analysis in biochemical research to acting as a superconsultant in the care of patients, was announced today by Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine.

"It will be one of the largest installations in a medical school," Dr. Glaser said, "with a memory almost equal to all computers now available at Stanford. Organized so that it will complement rather than duplicate existing services, the new computer will eventually provide a compendium of medical knowledge already far too great for any individual physician or researcher to keep in his mind."

The new program, which will be known as Advanced Computer for Medical Research, has been made possible by a grant of $445,000 for the first year from the division of research facilities and resources of the National Institutes of Health. A planning grant of $80,000 from the Josiah Macy Jr. Foundation of New York provided the impetus for the initial planning and staffing.

The computer was manufactured by International Business Machines Corporation. The computer program, far more ambitious than the other known undertakings in medical uses of computers, will be developed at Stanford.

The responsible investigator for the project is Dr. Joshua Lederberg, Nobel Prize winning geneticist and professor and head of the Department of Genetics. He will chair a committee of scientists from key Medical School departments and the Stanford Computation Center, who will coordinate the activities and use of the system.

The intent of Stanford's medical computer, Dr. Lederberg explained, is to develop techniques that will substantially increase and improve collection and analysis of results of many experiments from different laboratories simultaneously.

As new programs are put into the computer and their value tested, they will become available from the Stanford Computation Center, while the medical installation will be used for further systems research and other special applications.

Through the process of "time-sharing," the medical computer will constantly monitor scores of scientists' instruments, which will be located in the Medical Center and connected by cables to the machine. The system will permit a dialogue between doctor and computer during the experiments.

-MORE-

For example, Stanford anesthesiologists are now developing methods of direct connection between patient and computer while surgery is underway so that surgeons will almost have forewarning of heart failure and be able to act to head off the effects and save the patient.

Beyond this stage, the investigators see almost unlimited research possibilities for use of mathematical processes in diagnosing and treating heart disease.

One such method, developed by a Stanford researcher, will enable physicians to analyze electrocardiograms by mathematical accuracy greater than visual analysis which now might vary from doctor to doctor. Other uses of the medical computer will include:

--Studies of the mechanisms of normal breathing. When a person breathes, many events take place at once. It is possible to record each of these (such as rate of air intake and lung expansion, and changes in pressure intake within the chest) and analyze them by feeding the data into the computer.

--Behavioral studies related to brain function and mental development.

--Neurophysiological studies of the pattern of discharge in single nerve cells in the brain which may lead to a better understanding of sensory and learning processes; also research in the cellular processes which are involved in the production and control of abnormal electrical discharge in epileptic patients.

--Studies of the effects of a variety of environments such as polluted air on human breathing.

--A program, supported by the National Aeronautics and Space Administration, which will apply methods of medical research on proposed missions for the biological exploration of space.

Plans are also under way to develop a computerized medical reference library which will give physicians answers to basic decisions they must make by a process of ruling out everything that is not pertinent.

In addition, the computer has a great potential for medical education. Medical students, for example, eventually might use the computer system for training exercises with computer-simulated "patients" who could be assigned virtually any set of symptoms known to medicine.

Gio Wiederhold will be associate director of the advanced medical computer facility.

The Stanford University School of Medicine will inaugurate its second season of public lectures on "Progress in Medicine" Wednesday (October 26).

Dr. Avram Goldstein, professor and executive head of the Department of Pharmacology, will discuss "Drugs and How They Act" at 8 p.m. in Room M106 of the Medical School Building.

The lectures, featuring members of the Stanford medical school faculty and distinguished visiting professors, will be given each Wednesday during the academic year from 8 to 9 p.m. in the same location. Each department will offer three to four lectures.

Although the lectures are offered primarily for the community as a public service, Stanford undergraduates may enroll for credit, according to Dr. LeRoy A. Pesch, associate dean.

The lectures were initiated a year ago by Dr. Joshua Lederberg, Nobel Prize winning geneticist, "in the hope of giving an opportunity to leaders in academic medicine to share their own insight and perspective with the community." Again this year Dr. Lederberg will present some of the lectures.

"Today many exciting developments in medicine are being brought into being in laboratories and hospitals throughout the world," Dr. Lederberg said. "Public understanding of these developments is of the utmost importance for intelligent participation in important social decisions."

"Some of the decisions have to do not only with community health and with the public investment in medical research, but also with long range problems of world population, the management of artificial and transplanted organs, and the applications of the new knowledge of cell biology and heredity," Dr. Lederberg said.

Under Dr. Goldstein's direction the Department of Pharmacology conducts a broad program of research into the mechanism of action of drugs--anti-cancer agents, antibiotics, hormones and other substances that regulate metabolic activity, and drugs that affect the mind.

-MORE-

Stanford pharmacologists are also active in training predoctoral and postdoctoral students to meet the urgent national need for pharmacologists, at a time when the effects of drugs and environmental chemical agents are of increasing concern to society.

Dr. Goldstein's own research has been concerned with understanding the fundamental mechanisms of drug action upon enzymes, genes, and the synthesis of proteins and nucleic acids. His present research activities concern the biochemical changes underlying drug addiction and drug tolerance.

Dr. Goldstein came to Stanford in 1955 from Harvard Medical School where he served on the faculty. He received the A.B. from Harvard University in 1940 and the M.D. from Harvard Medical School in 1943. He is the author of numerous professional publications and editor of the international scientific journal "Molecular Pharmacology."

Other lectures in the series for November include:

November 2, "The Search for Animal Models of Human Disease," by Dr. Keith F. Killam, associate professor of pharmacology.

November 9, "The Case of the Venezuelan Nut," by Dr. Lewis Aronow, associate professor of pharmacology.

November 16, "The Use of Drugs in Population Control," by Dr. Sumner M. Kalman, associate professor of pharmacology.

The Palo Alto-Stanford Hospital Center announced today that Samuel S. Virts has been appointed assistant director. His initial responsibilities will include community, personnel and patient relations and hospital communications.

Mr. Virts received his Bachelor of Science degree from Northwestern University in 1947. For the past 11 years he served as assistant administrator of O'Connor Hospital in San Jose. Previously he was director of personnel at St. Mary's Hospital in San Francisco, and director of personnel and public relations, St. Mary's Hospital, Evansville, Indiana.

He has held the offices of president of the Hospital Council of Northern California, president of the Central Coast Hospital Conference, chairman of the committee on public education of the California Hospital Association and vice-chairman of the Hospital Commission of Santa Clara County.

An active member of numerous civic and service organizations, Mr. Virts has served as chairman of the San Jose Chapter, American Red Cross; chairman of Blood Donor Recruitment, Four County Regional Blood Center and secretary of the San Jose Branch of the American Cancer Society. He was named distinguished citizen of San Jose in 1958.

Mr. Virts resides at 982 Hilmar Street in Santa Clara with his wife and 5 children.

FOR PM RELEASE FRIDAY OCTOBER 21, 1966

Two Stanford University surgeons today reported they revived and implanted successfully cadaver dog hearts in 10 canine patients.

The dogs lived from eight to 38 hours, the surgeons said, but were it not for the limited nature of the experiments, the transplanted hearts would have functioned longer on the basis of observations made during the survival periods.

Dr. Robert D. Wuerflein, postdoctoral fellow in surgery, and Dr. Norman E. Shumway, chief of the division of cardiovascular surgery at Stanford University School of Medicine, termed the research an important step in learning how to remove hearts from cadavers, "banking" them and then restoring them to function.

They reported their findings at the scientific sessions of the American Heart Association in New York City.

The Stanford scientists said that one of the experimental goals was to determine how long after death hearts might be resuscitated when a minimum effort is expended in protecting them.

Accordingly, no effort was made to cool the heart of the experimental animals used in the studies, or to provide them with oxygen for varying periods after death.

Even under these conditions, Drs. Wuerflein and Shumway reported, good function could be restored in four cases out of five one hour after death. After an hour and a half of such planned "neglect," the salvage rate was seven out of 10. After two hours, all salvage efforts were unsuccessful.

"While transplantation of the canine heart has been established as a technically feasible procedure," the Stanford surgeons explained, "the two major stumbling blocks for human application are immunological barriers (the rejection of the foreign organ by the body), and procurement and storage of the donor organ."

-MORE-

The surgeons noted that "except for rare circumstances at present the source of donor hearts for human application must be a cadaver. The first problem of procurement of the donor heart needs a precise definition of how long the heart, which normally requires large quantities of oxygen, can survive outside the body.

"The next stage is to determine the best method of resuscitation and storage and then to attempt transplantation of the stored heart."

The Stanford surgeons tried various approaches. One that proved successful was to remove the heart together with the lungs and trachea (windpipe) as a unit, followed by immersion of the entire ensemble in a special bath to keep it moist and at a constant temperature. Then the windpipe was connected to a mechanical respirator, which supplied oxygen-rich air, and the lungs started "breathing" again.

In 15 to 30 minutes, good heart function was restored. These heart-lung "preparations" were then maintained for periods of from six to 30 hours before an effort was made to perform the transplantation.

Ten hearts thus restored to good function were transplanted into healthy dogs where they proved able to take over circulation, the Stanford surgeons reported. Four transplants functioned adequately for 38 hours.

FOR PM RELEASE MONDAY OCTOBER 17.

A dedication ceremony held at Palo Alto-Stanford Hospital Center today marked the official opening of the new blood bank facilities which were made possible by a $30,000 gift from the Hospital Auxiliary.

Mrs. Alvin Cox, president of the Auxiliary, presented the blood bank facilities to the Hospital Center along with the first unit of blood drawn which was donated by Mrs. Donald Campbell, Auxiliary board member. This was Mrs. Campbell's first blood donation since World War II and she was "impressed with the speed and comfort of the process."

Mr. Robert Klein, president of the Hospital Board, complimented the Auxiliary members for the outstanding assistance they have provided the Hospital Center during the past year. In addition to the blood bank, they have also donated an artificial kidney unit and the coronary care unit recently put into service.

The blood bank, one of only 43 in California and one of the few operated by a hospital, is equipped to draw blood from donors, type, process and store it in temperature-controlled refrigerators until it is needed by sick or injured patients.

Dr. Edmund J. Mahon, a San Francisco physician, has been named chairman of the 1966 Annual Fund Advance Gift Program for the Stanford University School of Medicine.

Under Dr. Mahon's direction, volunteers in San Francisco will solicit Stanford Medical Alumni during the six-week medical fund drive which begins October 18.

With research grants, tuition and student fees meeting part of its operating budget, the Stanford Medical School must count on endowment earnings and private gifts for a significant share of its operating costs. The fund drive for the School is part of the Stanford Annual Fund, started 30 years ago to help provide such support.

This year the Fund seeks to raise $1.4 million in unrestricted gifts to the University, including Medical School support.

Dr. Mahon was graduated from Stanford Medical School in 1930. He also served on the Medical School faculty from 1935 to 1955. He lives with his wife, Mary Anne, and daughter, Judith, at 39 Mirabel Avenue in Mill Valley, California.

The Stanford University School of Medicine, rated among the top nine medical schools in the United States, began modestly in San Francisco in 1882 as the Cooper Medical College. Today it occupies with its laboratories, hospital and clinics, the equivalent of two city blocks on the Stanford University campus.

The School has a full-time faculty of 300; a clinical faculty numbering 640; more than 300 men and women pursuing the course leading to the M.D.; 125 Ph.D. candidates; and 450 individuals pursuing advanced programs such as internships, residencies, and postdoctoral fellowships.

An automated blood analyzer that will perform 12 different chemical tests simultaneously is now in operation at the Palo Alto-Stanford Hospital Center.

The new $30,000 machine will speed up the processing of chemical laboratory tests and substantially reduce their cost to patients, according to Dr. Frederick A. Fox, director of clinical laboratories.

The machine can perform one battery of 12 tests every two minutes, Dr. Fox said. "Before the machine was available, it would have taken one medical technologist approximately four to six hours to perform the same 12 tests."

In addition, the 12 tests would normally cost $76, but now cost $18.

The tests are those most commonly ordered by physicians to assist them in the diagnosis and treatment of patients. Dr. Fox noted that within recent years there has been an increased use of such test batteries for health screening.

"When the tests are used in conjunction with annual physical examinations it is often possible to detect diseases before they become evident to the patient and thus allow for earlier treatment," he said.

Dr. Fox emphasized the need for automation of Palo Alto-Stanford's clinical laboratories to meet the increasing demand for blood chemistry tests and to compensate for the current nationwide shortage of medical technologists.

"Hopefully," he added, "such equipment will free technologists to perform more complicated tests and to participate in the development of new tests." One technologist can operate the new machine, although another is usually on hand for assistance if necessary.

-MORE-

The machine, known as an SMA-12, is fed samples of blood serum from plastic cups placed in a circular pick-up tray. The samples are pumped through an elaborate maze of plastic and glass tubing until they reach a programmed colorimeter which reads the final results.

The results of all 12 tests are automatically recorded on a single graph within 12 minutes after the sample enters the machine. Because of the sequential arrangement of the samples, six are in the system at any given time, allowing the machine to produce one battery of 12 tests every two minutes.

Dr. Fox and his staff tested the machine for six weeks before it was placed in operation. They found the machine's results were more accurate than those determined by manual methods and comparable to those produced by single channel automated equipment.

Dr. Richard B. Compton, a Pasadena surgeon, has been named regional chairman of the 1966 Annual Fund Advance Gift Program for the Stanford University School of Medicine.

Under his direction, volunteers in the Los Angeles area will solicit Stanford medical alumni during the six-week medical fund drive which begins October 17.

With research grants, tuition and student fees meeting part of its operating budget, the Stanford Medical School must count on endowment earnings and private gifts for a significant share of its operating costs. The fund drive for the School is part of the Stanford Annual Fund, started 30 years ago to help provide such support.

This year the Fund seeks to raise $1.4 million in unrestricted gifts to the University, including Medical School support.

According to Dr. Robert J. Glaser, vice president for medical affairs and dean of the Medical School, the School's budget has increased six-fold in the past 10 years, but most of the increase reflects grant support (chiefly from the National Institutes of Health). Important as this support has been the failure of private gift support to grow has created a serious "hard money" deficit..

"The private medical schools like Stanford," Dr. Glaser said, "have had a unique role of leadership in American medical education. This role has resulted from the independence and flexibility that has characterized the privately-supported institutions of higher learning. If we are to continue to lead--and in my view we must if we are to justify our existence to the fullest--then it is clear that gift resources have to be strengthened."

Surgical procedures will be telecast live and in color from the Palo Alto-Stanford Hospital Center during the 52nd annual Clinical Congress of the Americal College of Surgeons in San Francisco Monday through Friday (October 10-14).

Produced and sponsored by Smith, Kline and French Laboratories in Philadelphia, this section of the five-day program is under the direction of Dr. Roy B. Cohn, professor of surgery at Stanford University School of Medicine, in association with Dr. Harris B. Shumacker of Indianapolis.

This is the second time that telecasts have originated at Palo Alto-Stanford Hospital Center, the first being in 1960.

A 23-member medical color television unit will televise surgeries performed at the Hospital to viewers in Polk Hall at the Civic Auditorium in San Francisco.

Fourteen operations will be performed by members of the Medical School faculty and surgeons from the Palo Alto community and will be discussed by special panels of surgeons at the meeting.

More than 12,000 members of the College and guests from many countries are expected to attend the meeting and review new surgical developments.

Editors: Photographs are available on request.

A new blood bank to meet the Peninsula's growing needs for blood and blood products has just opened at the Palo Alto-Stanford Hospital Center.

Dedication ceremonies are planned for October 17 at 11:30 a.m., followed by an open house and tour.

The bank and related blood drawing facilities were made possible by a $30,000 gift from the Hospital Center Auxiliary. The money came from the profits of the Auxiliary's Gift Shop in the Hospital.

The laboratory facilities of the bank have been in use since early June, but blood could not be drawn there until the State Department of Public Health had inspected and licensed the unit.

The laboratory is used to crossmatch blood from donors and recipients. Every unit must be carefully typed to avoid a transfusion reaction in the recipient. Such a reaction may occur if a patient is given blood of a type different than his own.

Dr. Frederick A. Fox, who is in charge of the blood bank, said the Palo Alto-Stanford Hospital Center will use 11,000 units of blood this year. Just a year ago the total was only 8,500 units.

To help meet this rapidly growing need, the Hospital Center is cooperating with the newly formed Community Blood Reserve of Palo Alto. CBR is a blood assurance program which will guarantee a supply of blood for its members.

When CBR members are called upon for blood donations, they will give blood at the Hospital Center's blood bank. CBR is continuing to solicit members; the program officially went into effect with the licensing of the blood bank.

-MORE-

One of the reasons the demand for blood has increased so much is that there are now between 25 and 30 open heart operations in the Palo Alto-Stanford Hospital Center each month. Each open heart case requires from 10 to 18 units of blood. The blood must have been drawn within 24 hours of the operation as well.

Fresh blood is only one of the needs of the Hospital's patients. Because of the highly specialized medical and surgical services available, there are frequent calls for special types which are difficult to locate because only a small percent of the population has them. Many times some blood fraction is needed instead of whole blood. Such a fraction may contain only red blood cells, or platelets, or have the white cells removed, for instance.

The new blood bank includes a special area in which blood is drawn. There are two donor chairs, each shaped like contour chairs and equipped with a special device which keeps the blood mixed so it will not clot. The device also stops blood flow when one pint has been drawn.

The laboratory area includes refrigerators in which the donated blood is stored, centrifuges and other equipment for crossmatching, and provides space for three medical technologists.

STANFORD -- A series of six public lectures on recent advances in surgery will begin Wednesday (November 30) at Stanford University School of Medicine.

Dr. James M. Guernsey, instructor in surgery, will present the first lecture on "Advanced Tumors" at 8 p.m. in Room M106 of the Medical School Building.

Dr. Guernsey will describe various ways of treating cancer, specifically breast cancer and advanced head and neck cancers. He will illustrate his talk with slides and examples from case histories.

The lectures are part of the medical school's PROGRESS IN MEDICINE series initiated last year by Dr. Joshua Lederberg, Nobel Prize winning geneticist and head of the Department of Genetics. Each medical school department will present three to six lectures.

Although the lectures are offered primarily for the community as a public service, Stanford undergraduates may enroll for credit.

Dr. Guernsey has been a member of the Stanford faculty since 1965. He obtained both his undergraduate and M.D. degrees at Stanford and completed residency training at the medical school.

The Department of Surgery has announced the following schedule for the other five lectures:

DECEMBER 7: "Plastic and Reconstructive Surgery," by Dr. Robert A. Chase, professor and head of the Department of Surgery, and Dr. Donald R. Laub, instructor in surgery.

DECEMBER 14: "Why Doesn't the Stomach Digest Itself?," by Dr. Harry A. Oberhelman Jr., professor of surgery, and Dr. George R. Mason, instructor in surgery.

JANUARY 11: "The Artificial Kidney," by Dr. John M. Palmer, assistant professor of surgery.

JANUARY 18: "Heart Surgery," by Dr. Edward J. Hurley, assistant professor of surgery.

JANUARY 25: "Kidney Transplantation," by Dr. Roy B. Cohn, professor of surgery, and Dr. Samuel L. Kountz, assistant professor of surgery.

The Board of Directors of the Palo Alto-Stanford Hospital Center has awarded a $146,398 contract for construction of additional physicians' on-call quarters to Welch Construction Company of Menlo Park. Announcement of the contract award was made by Frank Vitale, Associate Director of the Hospital Center.

Lowest in a field of nine competitors, Welch won the bid for an expansion project which will more than double the lounge and sleeping facilities for residents and interns on duty at the hospital during the on-call hours of 5 p.m. to 8 a.m.

According to Vitale, plans call for the new quarters to be constructed atop the West Wing of the Hospital Center. The addition will cover 4,424 square feet and will contain 21 single rooms and two double rooms that have either patio or outside exposures. Facilities include a lounge with separate reading and television areas and room for ping pong or pool tables.

By constructing additional quarters for its on-call staff, the hospital hopes to improve and expand its on-call service. Present on-call quarters can accomodate only 17 of the 25 physicians assigned to nightly duty at Palo Alto-Stanford Hospital Center. The hospital also staffs an on-call complement of approximately 34 other medically-trained personnel to provide for round-the-clock specialists in 32 different fields.

Under the present set-up, severe limitations in sleeping space have often forced on-call personnel to use make-shift sleeping quarters set up in classrooms or other unoccupied areas.

Dr. David L. Bassett, 53, former professor of anatomy at Stanford University School of Medicine, died Thursday at the University of Washington Hospital in Seattle after a long illness.

Dr. Bassett, widely known for his pioneer work in developing photographic three-dimensional studies of human anatomy, was a professor of gross anatomy in the Department of Biological Structure of the University of Washington School of Medicine. He moved to Seattle from Stanford in 1959.

Dr. Bassett had taught at Stanford Medical School since 1939. With William B. Gruber of Sawyer's Inc., he authored in 1952 "A Stereoscopic Atlas of Human Anatomy," a unique four-book atlas of anatomy which makes use of stereoscopic color transparencies.

Last year the graduating class at the University of Washington School of Medicine named Dr. Bassett as "the outstanding teacher in basic sciences."

He received his B.S. degree in 1934 and M.D. degree in 1939 from Stanford. His father, Dr. Lee Emerson Bassett, who died in 1959, was professor emeritus of speech and drama. He had organized Stanford's Department of Speech and Drama and taught there for 35 years.

Dr. Bassett is survived by his wife, Lucille, a daughter, Roberta, and two sons, Lee and William.

Memorial services for Dr. Bassett will be held Saturday in Seattle, Wash.

STANFORD -- "Probably the most widely practiced form of birth control today is not a contraceptive method, but abortion," a Stanford University pharmacologist said Wednesday night.

Ironically, abortion is practiced at a time when new and effective birth control methods are available and more are being developed such as drugs that will induce temporary male sterilization and possibly, in the more distant future, a vaccine against pregnancy.

Dr. Sumner M. Kalman, associate professor of pharmacology at Stanford University School of Medicine, said "no government as far as I know advocates abortion as a desirable method of population control although it is legal in several countries."

But the number of abortions in Santiago, Chile, for example, is estimated at about half of the number of births, and abortion is illegal in Chile, he said.

In Japan in the late 1940's, there were a large number of illegal abortions, resulting in suffering and maternal death. Legislation which legalized abortion was not intended to control population increase, but to bring a public health problem under medical control.

The number of illegal abortions performed in the United States each year is not known, he said. Most estimates place it close to one million or one abortion for each six live births.

Yet birth control methods have been used in trials in the underdeveloped areas of the world, and are still made freely available where adequate facilities exist, Dr. Kalman said.

Of the devices tested, the contraceptive pill is potentially the most effective, Dr. Kalman said, mainly because it is simple, easy to take, and does not have to be used at the time of sexual intercourse.

"But the very impressive early results with this approach should not blind us to the need for other drugs and devices," he said.

"In Colombia, for instance, the pills failed simply because there is no place to keep them in the home, even if the somewhat complex schedule of taking the drug could be followed."

Dr. Kalman made his remarks at the "Progress in Medicine" lecture series, presented each Wednesday by faculty members of the School of Medicine for the public. His topic was "Use of Drugs in Population Control."

He cited estimates showing that contraceptive pills are gaining acceptance in the United States. About twenty-five percent of women of childbearing age who use contraception are using "the pill."

Oral contraceptives act through suppression of the pituitary gland so that the usual complex pattern of hormone secretion needed for ovulation is upset.

"Thus far no serious toxic effects have been demonstrated, and, at the present time, the drugs are considered safe," Dr. Kalman said.

-more-

He noted that additional actions of the "pills" have been observed. For example, secretions in the cervix become thick and less rapidly penetrated by male sperm, and also the inner lining of the uterus is not properly prepared for implantation of the young embryo.

He cited results of a study done in Puerto Rico in which placebos ("dummy pills") and oral contraceptives were given to two groups of women. Annoying side effects such as nausea, headache were reported by both groups with no significant difference indicating perhaps that these side effects are partly due to fear of this novel contraceptive method.

Dr. Kalman said that in addition to the pills, there has been a renewed interest in intrauterine devices. "They are not as effective as the pills but they are acceptable to public health officials who want to see some effect on the birth rate," Dr. Kalman said.

The Stanford pharmacologist said that while the population of 3 billion in the world today will double in 45 years, it will increase only 50 percent in the more developed areas and by more than 100 percent in the underdeveloped countries. The per capita income for the poorer countries will decline, and their level of nutrition will become worse.

"We can help by providing expert help in both fields, by training people from the underdeveloped countries and by contributing money and food as they are needed," he said.

"But basic and applied research in reproductive physiology and pharmacology of contraception would pay far greater dividends than any other research the government could support. Not only new contraceptive techniques are needed, but also studies of motivation are completely lacking."

Some new approaches listed by Dr. Kalman included:

-- drugs which induce male sterility for fairly long periods of time, the effect being reversible.

-- a synthetic estrogen (sex hormone) that blocks release of pituitary hormones needed for ovulation to occur.

-- use of sex hormones to prevent fertilization after intercourse.

-- a vaccine that would prevent fertilization much in the same way as the body fights a virus.

It has been found, Dr. Kalman said, that a female guinea pig may be immunized so that fertilization by the male is reduced or does not occur. The immunizing agent was a suspension of male sperm cells injected into the female. It was possible to show that there are circulating antibodies in the female guinea pig and also reduction of pregnancies.

Editors: Photo available on request.

STANFORD -- A rare operation in which a physician donated his kidney to save a nurse dying of kidney failure was disclosed today by Stanford University surgeons.

The physician, Dr. Philip Avet, 30, a pathology resident at Louisiana State University School of Medicine, returned to New Orleans Tuesday, only a week after one of his healthy kidneys was removed and transplanted to his sister, Mrs. Marie W. Ooton, 28, of Mountain View, Calif.

"I feel perfectly healthy," said Mrs. Ooton. "I am gaining my strength back. I haven't felt better in years." Surgeons said her new kidney is functioning normally. Dr. Avet and Mrs. Ooton were patients at the Guggenhime General Clinical Research Center of the Stanford University School of Medicine.

On the day the transplant was performed at Stanford, Dr. Avet's wife, Marilyn, gave birth to a baby named Patrick at Charity Hospital in New Orleans. The Avets also have an 18-month-old daughter.

Mrs. Ooton, a registered nurse and former Medical Center employee, had suffered from fatal kidney disease since 1960. Unable to raise the $15,000 needed to buy a home artificial kidney machine, Mrs. Ooton and her physicians agreed that a kidney transplant was necessary to save her life.

Transplantation of kidneys from one human to another, however, is still highly experimental and the surgeons wanted to make sure that the donor and the recipient were familiar with the risk of the operation. Results so far have been encouraging in kidney transplants among relatives, but have been poor among unrelated persons, they explained. The carefully selected related patients, given intensive treatment to subdue the body's natural antagonism to foreign tissue, can now live longer with newer and more effective techniques.

-MORE-

In spite of the risk of surgery, his wife's pregnancy, and the then unknown factors about his sister's disease, Dr. Avet decided to go ahead with the operation.

"I had no real difficulty deciding," he said. "When I was called to come to Palo Alto, my sister was dying. I always felt close to my sister and believed I owed her a fighting chance. Now I know I made the right choice."

The Stanford surgeons said they have used a slightly modified technique of controlling rejection of the kidney by the host body. The technique was reported last month at the International Congress of Nephrology in Washington, D.C. by members of the Department of Surgery.

The method consists of injecting immunosuppressive drugs via a catheter directly into the kidney. It enables the surgeons to reverse the rejection reaction at the site where it occurs in the transplanted organ. With previous techniques, drugs given orally suppressed the immunity of the entire body and the patient was susceptible to infection.

This was the 11th successful kidney transplant among relatives since the program began at Stanford more than two and a half years ago. It was the first transplant in which a physician was the donor and a nurse the recipient. All of the patients now live normal lives.

Mrs. Ooton lives with her husband, Thomas, a sanitation engineer, and their 20-month-old son, Timothy, at 891 Rengstorff in Mountain View.

The Avets live at 1900 Perdido Street in New Orleans, La.

STANFORD -- Dr. Philip R. Lee, assistant secretary for Health and Scientific Affairs of the U.S. Department of Health, Education and Welfare at Washington, D.C., will be the principal speaker at the annual Big Game Get-Together of the Stanford Medical Alumni Association Friday (November 18).

Dr. Lee will speak on "Public-Private Partnership for Medical Care" at an alumni-faculty luncheon in the Cabana Hotel at Palo Alto.

The day-long meeting will begin with registration at 9:30 a.m. in the Medical School Courtyard, followed by combined Grand Rounds by the clinical departments of the School of Medicine in Room M106.

Presiding at the luncheon will be Dr. Henry Gibbons, III, of San Francisco, president of the Stanford Medical Alumni Association. He will introduce Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine, who will discuss "The State of the Medical School."

Dr. Lee was graduated from the Stanford Medical School in 1948 and is a specialist in internal medicine. He was on the Palo Alto Medical Clinic staff from 1956 to 1963 and is an assistant clinical professor of medicine at Stanford. Now on leave from the Clinic and from Stanford, he has been serving as the highest-ranking physician on the staff that administers the medicare program.

"The Use of Drugs in Population Control" will be the subject of the Wednesday (Nov. 16) public lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

Dr. Sumner M. Kalman, associate professor of pharmacology, will speak at 8 p.m. in Room M106. This is the last of four lectures presented by the Department of Pharmacology. The next six lectures, beginning November 30, will be sponsored by the Department of Surgery.

Dr. Kalman will discuss the problem of population growth in underdeveloped areas of the world, briefly review human reproductive physiology, and describe current research on population control.

The speaker's interest in population control is an outgrowth of several years study of sex hormones. He is currently conducting a seminar on the topic for Stanford students.

Dr. Kalman received his M.D. from Stanford in 1950 and has been a member of the faculty since 1954.

STANFORD-- Electric shock directly applied to the chest can successfully restore normal heart beat in patients with implanted artificial mitral valves, according to two Stanford University physicians.

Dr. Blaine Braniff, postdoctoral fellow in medicine, and Dr. Herbert N. Hultgren, associate professor and chief of the division of cardiology at the School of Medicine, reported that they were able to restore normal heart rhythm in 41 of 60 patients with atrial fibrillation in which the technique was used.

"After an average follow-up period of 10 months 24 of the patients treated still had a normal heart beat," the physicians said.

A major problem in mitral valve replacement was that many of these patients' heart beat would remain irregular after surgery. The condition, if left untreated, could lead to clot formation and strokes. There are more than 10,000 patients in the United States who are alive today with artificial valves.

Drs. Braniff and Hultgren said they had less success in restoring normal heart beat in patients who had irregular rhythm for more than five years before mitral valve replacement. These patients, they explained, develop a weak and enlarged left atrium or pumping chamber as a result of prolonged faulty valve function, and the abnormal rhythm that results is not as easily corrected.

The technique, known as cardioversion,is applied under anesthesia. Two electrodes are placed on the anterior chest and between the patient's shoulder blades. The electric shock, traveling through the heart between the two electrodes, stops it momentarily from beating and allows the normal pacemaker to resume activity.

Restoration of normal heart rhythm has been carried on previously with drugs, but the new technique is now uniformly accepted throughout the country.

Drs. Braniff and Hultgren presented their findings at the fall symposium of the Guggenhime Clinical Research Center at Stanford.

Members of the South Palo Alto Lions Club today sent a 3,000 pound crate of medical equipment to India.

The equipment, valued at $5,000, is going to Dr. Radha Pant, assistant professor of biochemistry at the University of Allahabad and former research associate at Stanford University School of Medicine.

Mostly used and surplus items, the equipment was given to Dr. Pant by the medical school, the Palo Alto Medical Research Foundation, Calbiochem, Varian Associates and private donors. Dr. Pant requested the supplies to help further her research on the nutritive value of beans and the output of silk worms.

The Lions Club contributed $1,000 for transportation costs and made all packaging and shipping arrangements, with the assistance of the Palo Alto Transfer and Storage Company and the Oceanic Forwarding Company in San Francisco.

The crate will be shipped November 14 from Oakland aboard the Scandia Lines. It is expected to arrive in Calcutta January 7, and arrangements have been made with a Lions Club there to assure its safe delivery to Allahabad.

CALIFORNIA COMMITTEE ON REGIONAL MEDICAL PROGRAMS
HEART, CANCER AND STROKE

Temporary address:

Department of Chronic Diseases
Department of Public Health
2151 Berkeley Way
Berkeley, California

Editors: Story transmitted on Business Wire 11/10/66.

FOR FURTHER INFORMATION CONTACT: Nemat O. Borhani, M.D. (Area Code 415) 843-7900

A three-year grant has been awarded to the State of California from the National Institutes of Health to establish planning activities for the development of a Regional Medical Program to improve the level of diagnosis and treatment of heart disease, cancer, stroke and related diseases.

The program will be coordinated by the California Committee on Regional Medical Programs, a state-wide voluntary committee formed to assist medical schools and hospitals in the development of cooperative medical programs under the new federal legislation.

The announcement, made today by Committee Chairman Dr. Robert J. Glaser, vice-president for medical affairs and dean of the Stanford University School of Medicine, said that the grant for the first year is in the amount of $223,400. It is expected that the three-year planning program will be funded with a total of some $650,000.

The fiscal agent for the grant will be the California Medical Education and Research Foundation, a nonprofit organization of the California Medical Association.

The law under which the grant was made is administered by the Division of Regional Medical Programs of the National Institutes of Health. Its purpose is to give the medical profession and medical institutions, through cooperative arrangements, the opportunity to make available to their patients the latest advances in diagnosis and treatment of heart, cancer, and stroke and other major diseases.

-MORE-

"We are delighted to acknowledge the grant award to the California region," said Dr. Robert Q. Marston, associate director of the National Institutes of Health and Director of the Division of Regional Medical Programs. "This grant makes another significant step toward one of the first goals of the legislation which established the regional programs. It brings another large and important region into the total effort to provide the entire country and all of its people with the opportunity to participate in the potential benefits inherent in the ultimate purposes of the Regional Medical Programs.

"It also reflects the intent of the law as a program is generated at the local level. In this way, all of the health professions of the region are brought together with the major health, research, service, and civic organizations and institutions."

The planning grant, according to Dr. Glaser, is to help the California Committee on Regional Medical Programs undertake:

--studies pertinent to coordinating regional programs,

--investigation of mortality trends, prevalence and incidence of heart disease, cancer and stroke.

--manpower studies to determine how medical care is now being provided to patients in California.

From these studies the California Committee will develop guidelines in the establishment of the regional programs throughout the state. The studies will be conducted by a full-time staff to be employed and located in San Francisco.

Dr. Glaser emphasized that each regional program planned and organized under local leadership will be developed independently by medical schools, research institutions and community hospitals. The committee, through its broad representation, will serve as a valuable resource in the development of regional programs. It will review and approve all institutional applications for heart, cancer, and stroke programs to prevent activities with conflicting purposes, duplication, and gaps.

In addition to Dr. Glaser, the officers of the state committee are Dr. Ralph C. Teall, California Medical Association, vice-chairman, and Mark Berke, California Hospital Association, secretary-treasurer. The committee has 19 members.

FOR PM RELEASE THURSDAY, NOVEMBER 10, 1966

STANFORD -- Is hemophilia caused by accelerated destruction of the blood clotting protein in circulation or by body failure to synthesize enough of the substance?

This question has been a subject of prolonged debate among medical researchers, but today a Stanford Medical School investigator presented evidence supporting the latter view.

Dr. Judith G. Pool, senior research associate in medicine, told the fall symposium of the Guggenhime General Clinical Research Center that normal persons destroy antihemophilic globulin (AHG) in their circulation at least as rapidly as hemophilic patients.

"It is, therefore, certain that the disease is caused by a failure of the body to synthesize antihemophilic globulin," she said.

Dr. Pool reported studies on two normal volunteers who received transfusions of a large quantity of concentrated AHG prepared from their own plasma. Identical results on both individuals showed that AHG had a half-life of about two and a half hours in their circulation as compared to about 13 hours in hemophiliacs.

Although the decay rate of AHG in hemophilic patients had been determined before, this is the first time such a study was undertaken on normal persons. This was made possible because of the availability of concentrated AHG, an area in which Dr. Pool and her associates have pioneered.

The concentrated AHG permits the scientists to raise the blood clotting protein level in the normal individual without overloading his circulation with liquid normally contained in whole plasma. An overloading of the circulatory system creates a state of nonequilibrium from which it is difficult to measure accurately the decay rate of AHG.

Dr. Pool said the finding has important implications for developing an effective treatment for hemophilia. "We no longer need to be concerned about inhibiting the so-called rapid destruction of AHG because there isn't rapid destruction. What we now need to do is to determine the site of AHG synthesis in the body, find out why the tissue is not performing its job in hemophiliacs and then hopefully correct the condition at birth." She suggested that transplantation of normal tissue from mother to the baby is a distinct possibility.

Hemophilia is a rare hereditary condition found almost exclusively in males. Victims of it lack one of the nine or ten plasma proteins responsible for making blood clot. Patients are very susceptible to injury, but more often bleeding occurs spontaneously, particularly in the joints of the legs and arms. As a result, boys with the condition are often crippled by the time they reach adolescence.

FOR PM RELEASE THURSDAY, NOVEMBER 10, 1966

STANFORD -- A Stanford University pediatric research team today reported a new finding that may lead to control of Hurler's disease or gargoylism, an inherited disorder which causes birth defects in one out of 10,000 babies in the United States.

The team, headed by Dr. Irwin A. Schafer, assistant professor of pediatrics at the School of Medicine, studied cultured cells from patients with Hurler's disease and found that vitamin C increased the production of sulfate mucopolysaccharides.

Mucopolysaccharides are chemical substances found in almost all tissue cells in the body. In Hurler's disease abnormally large amounts of these compounds are made by the cells and deposited in tissue, producing blindness, dwarfism, bone, spleen and liver abnormalities, heart defects and mental retardation.

Because of the patient's appearance the term gargoylism has been applied to the condition in the past. The compounds can be detected in urine samples from which a diagnosis of the disease is made. An affected child usually appears normal at birth and, in most cases, by the sixth month shows clinical signs of the disorder.

"When vitamin C was added to the cell cultures, the Hurler's cells produced an abnormally large quantity of mucopolysaccharides," Dr. Schafer said. "This suggests that vitamin C might be specifically involved in the synthesis of these compounds."

more

The research findings published recently in SCIENCE, the journal of the American Association for the Advancement of Science, show that vitamin C stimulated the synthesis of dermatan sulfate, the principal mucopolysaccharide found in excess in children with Hurler's disease.

Dr. Schafer reported on the research at the fall symposium of the Guggenhime General Clinical Research Center at Stanford. The research team included Dr. Julia C. Sullivan, research associate in pediatrics; Drs. Jiri Svejcar and Jorge Kofoed, postdoctoral fellows; and Dr. William van B. Robertson, professor of biochemistry in the Department of Pediatrics.

The study was supported in part by grants from the John A. Hartford Foundation of New York, the National Foundation, and the National Institutes of Health.

The Stanford researchers suggested it might be possible to control the disease by giving patients a diet devoid of vitamin C. They reported clinical studies of a seven and a half month-old baby who has been on such a diet for the past five months.

"The patient is doing well and shows normal growth and development", Dr. Schafer said, "but she continues to excrete the same amount of mucopolysaccharides in her urine. Because of the natural history of the disease, it will take at least another year of study before the results of the treatment are definitely known.

"We are puzzled by this child's response to a diet devoid of vitamin C. By chemical standards she is vitamin C deficient, yet shows no signs of scurvy. It is conceivable that patients with Hurler's disease have a unique metabolism for vitamin C which plays a role in this disorder."

CITY EDITORS AND SCIENCE WRITERS

On November 10 from 12 noon to 5 p.m. the Stanford University School of Medicine will sponsor a symposium on research activities at the Guggenhime General Clinical Research Center. The meeting will be in Room M106 of the Medical School Building

Among the participants will be Dr. Judith Pool, senior research associate in the department of medicine, who will discuss a new finding explaining how hemophiliacs destroy the blood fraction in the circulatory system, which is needed to prevent bleeding, Dr. Irwin A. Schafer, assistant professor of pediatrics, who will speak on a new treatment for controlling Hurler's disease, an inherited disorder which causes birth defects, and Dr. Henry Kaplan, professor of radiology, who will report on immunologic resistance in the treatment of Hodgkin's disease.

Research reports also will be presented on cardiovascular hypertension, epilepsy, and surgery for heart valve replacement.

The Guggenhime General Clinical Research Center is a 31-bed facility in the Stanford Medical Center. It has its own staff, laboratories, and facilities to provide the best possible conditions for scientists from many specialties to conduct rigidly controlled studies on specially selected patients. The work of the Center is supported by a continuing grant from the National Institutes of Health.

The search for an anticancer drug among the nuts of the Coco de Mono tree in Venezuela will be the subject of the Wednesday (Nov. 9) public lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

Dr. Lewis Aronow, associate professor of pharmacology, will speak on "The Case of the Venezuelan Nut", at 8 p.m. in Room M106 of the Medical School Building.

Dr. Aronow will describe his research which began three years ago in Venezuela and is continuing at Stanford.

The Coco de Mono bears a delicious nut, very much like a Brazil nut. However, nuts from some of the trees are poisonous and occasionally fatal. Those who eat them and survive suffer complete, if temporary, hair loss.

It was this symptom that Dr. Aronow particularly noted. Of the handful of substances which make people lose their hair, most are anticancer drugs.

Although subsequent investigation has shed no light on the treatment of cancer, Dr. Aronow's work has furthered scientific understanding in other areas and has produced an antidote for accidental poisoning.

Dr. Aronow has been a member of the Stanford faculty since 1956. He received his B.S. from the City College of New York, his M.S. from Georgetown University and his Ph.D. from Harvard University.

To ensure that patients hospitalized Election Day, Tuesday, November 8, can still register their voices at the polls, the Palo Alto-Stanford Hospital Center, in cooperation with its auxiliary and the Palo Alto and Sequoia chapters of the American Red Cross, has devised a special absentee ballot voting program.

Aided by auxiliary and Red Cross volunteers, the hospital plans to make absentee ballot request forms available to all registered voters of Santa Clara and San Mateo counties who enter the hospital by 9 o'clock ~~Monday~~ Tuesday morning.

Plans call for auxiliary members to collect the ballot request forms at the hospital. Red Cross drivers will then take these forms to the county clerk offices in Santa Clara or San Mateo counties and be given absentee ballot forms for the patients to use. On Tuesday, after Hospital Center patients have had the opportunity to vote, the completed ballots will be returned to the court houses for tabulating.

Provision for this type of absentee voting procedure is made in Section 14800 of the State Elections Code.

In addition to receiving the absentee ballot request form, all patients will also be given a covering letter from Dr. LeRoy E. Bates, Director of the Hospital Center. The letter explains the arrangements the Hospital Center has made for its local registered voters and concludes by stating that: "The right to vote is a precious heritage; the hospital is pleased to be able to help you exercise that right."

FOR A.M. RELEASE THURSDAY, DEC. 29, 1966

FILE COPY

WASHINGTON, D.C. - The American Association for the Advancement of Science Wednesday night announced that the 1966 Newcomb Cleveland Prize has been awarded to Dr. David S. Hogness, 41, professor of biochemistry at the Stanford University School of Medicine, for his contribution to the understanding of gene function in viruses and bacteria.

The $1,000 award and bronze medal were presented to Dr. Hogness at the 133rd AAAS annual meeting here for his paper "The Structure and Function of the DNA from Bacteriophage Lambda."

The paper described methods for isolating and studying genes in DNA from bacterial viruses. DNA or deoxyribonucleic acid is the storehouse of genetic information. It is found in the chromosomes of all cells and in many viruses. DNA plays the important role of transmitting the genes from generation to generation through its ability to produce exact replicas of itself.

One gene follows another in the very long thin virus DNA molecule or chromosome. By breaking up this chromosome into smaller fragments and studying the genes in each fragment, Dr. Hogness and his associates have determined the order in which genes occur in the DNA itself.

The information contained in each gene is read by the cell machinery in one direction or the other along the length of the DNA. Dr. Hogness reported experiments in which this direction was determined. Such studies may lead to a better understanding of the processes by which genes are switched on and off to give rise to the variety of different types of cells found in humans and other higher organisms.

A fuller understanding of gene interactions may lead to more basic knowledge of how the human body grows and develops, and how diseases affect these processes. A striking example of the genetic system's getting out of control is the rapid and unregulated cell growth in cancer.

The Newcomb Cleveland Prize is the senior award of the AAAS and was established in 1923 by Mr. Newcomb Cleveland of New York. It is awarded annually to the author of a noteworthy paper representing an outstanding contribution to science. The winner is selected by a committee of judges appointed by the AAAS board of directors.

A native of Oakland, California, Dr. Hogness is a graduate of the California Institute of Technology with a Ph.D. in chemistry. He came to Stanford in 1959 from Washington University in St.Louis, Mo., where he served as assistant professor in the Department of Microbiology. From 1952 to 1954 he worked as a postdoctoral fellow at the Pasteur Institute in Paris under Dr. Jacques Monod who won the Nobel Prize in 1965 for his theories of gene operation in DNA.

Dr. Hogness is the author of numerous papers in the fields of nucleic acids, protein synthesis, and genetics. He is a member of the American Society of Biological Chemists, Genetics Society of America, and a former member of the Advisory Panel on Molecular Biology of the National Science Foundation.

Dr. Hogness, his wife Judith, and two sons, Peter and Christopher, live on campus.

END ADVANCE FOR RELEASE TO A.M.'S THURSDAY, DEC. 29, 1966. ### 12/27/66

When demand goes up and supply goes down, somebody does without. You can use that principle to talk about automobiles, but not about human blood. Faced with an annual decrease in the number of blood donors and a predictable increase in need, officials at Palo Alto-Stanford Hospital Center are now entering "ulcer season."

Social activities and financial pressures take an annual holiday toll on ulcer-prone individuals. At the same time of year that their need for blood increases, automobile accidents mount and elective surgery goes on an upswing. It's easy to see why "ulcer season" means ulcers for blood bank officials as well.

Almost every local blood shortage can be related to a low rate of blood replacement. The friends or relatives of a patient who draws blood often fail to recognize their responsibility to replace that blood. But local citizens are also lax about building up a blood supply for the future. One hospital official blames this condition on the comparative affluence of the area. "Most people would just rather pay for blood when they need it than donate some now for a future emergency."

Around Christmastime, even the small number of regular donors tends to decrease. "We can't turn money into blood," blood bank officials will tell you. "We do, of course, charge a patient when the blood he uses isn't replaced by donations from his friends and relatives. But when the blood supply runs out, there just isn't any more blood available."

The Palo Alto-Stanford Hospital Center gets most of the blood it uses from either Peninsula Blood Bank in Burlingame, Irwin Memorial in San Francisco, or the Four County Regional Blood Center operated by the Red Cross in San Jose. Its own newly-established hospital blood bank supplies some fresh blood and blood for emergency situations. When a hospital's blood supply gets low, it can usually count on other hospitals in the area to lend a helping hand. But when every hospital's blood supply is low, as is the case every holiday season, the well-being of every patient and potential patient is endangered.

How can the average citizen help? By donating blood at any of the local blood-drawing facilities.

As blood bank officials enter their annual "ulcer season," they feel that the finest Christmas present anyone could give would be a gift of blood. ### 12/22/66

STANFORD -- The diagnosis and treatment of peptic ulcer will be the subject of the next public lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine.

Dr. Harry A. Oberhelman Jr., professor of surgery, and Dr. Robert Mason, instructor in surgery, will speak Wednesday (Dec. 14) at 8 p.m. in Room M106 of the Medical School Building. The title of their lecture is "Why Doesn't the Stomach Digest Itself?"

The two surgeons will describe the basic physiology of peptic ulcer, which may develop on the wall of the esophagus, stomach or small intestine. They will also discuss some of the recent advances in the surgical treatment of ulcers.

Dr. Oberhelman, a specialist in gastrointestinal surgery, has been a member of the Stanford faculty since 1960 and is the author of numerous publications on gastric secretion and peptic ulceration. Dr. Mason joined the faculty in 1965 after serving his residency in surgery at Stanford.

Blood donors are badly needed for a Redwood City man stricken with a rare bleeding disease, physicians at Palo Alto-Stanford Hospital Center reported today.

Technologists at the Hospital Center blood bank report that their supply of Type-O positive blood has been exhausted, and they have issued an urgent call for anyone who will donate blood.

The patient, Piet Van den Ende, 44, has used more than 100 pints of blood in the past month fighting internal bleeding from the small blood vessels in his stomach and intestines. He suffers from hemorrhagic telangiectasia, commonly known as Osler's disease.

A native of the Netherlands, Van den Ende has lived on the Peninsula for the past 24 years, and was employed by the Western Pacific Railroad before being stricken by the bleeding condition. Described by doctors as "a very courageous person," he has been hospitalized numerous times during the past two years, and during that time has received nearly 500 pints of whole blood.

Because he can lose up to 20 pints, or twice his total body blood supply, in a 24-hour period, it has been impossible for Van den Ende to find enough donors to replace the blood he has drawn.

Hospital Center technologists explained that although Van den Ende's blood type is Type-O positive, a blood donation of any type can be credited to Mr. Van den Ende. Donations may be made at Peninsula Blood Bank in Burlingame, Irwin Memorial in San Francisco, the mobile bloodmobile, or at the Hospital Center.

During the past month, 1,047 pints of blood were needed by patients at Palo Alto-Stanford Hospital Center. In that same period only 100 pints were donated to the Center's blood bank. As one official stated, "The Peninsula chronically suffers from a shortage of blood. Now, with the approach of the holiday season and a predictable increase in the number of automobile accidents, our shortage is especially acute."

Stanford University has awarded a $39,120 contract for construction of special housing for the medical research computer to Harrod and Williams, Inc., general contractors of Sunnyvale.

The powerful and versatile computer--an IBM 360/50--is being installed at the Stanford University School of Medicine to help doctors diagnose disease and explore new avenues of medical computer research.

The computer will be located in an 1,800 sq. ft. glass enclosure in the breezeway between the Medical School and the Clinical Sciences Research Building, and will be easily visible to visitors while in operation. The enclosure will be equipped with acoustic tile, and special ventilating and air conditioning system.

When it has been fully developed after three years and a cost of about $1.5 million, the computer will provide a compendium of medical knowledge far too great for any individual physician or researcher to keep in his mind, according to Dr. Robert J. Glaser, vice president for medical affairs and Dean of the School of Medicine.

The computer will analyze many experimental results from many different laboratories simultaneously. It will also process data from medical instruments hooked up to patients, enabling doctors to monitor critical body functions more accurately during surgery or acute illness.

Dr. Joshua Lederberg, Nobel prize winning geneticist and professor and head of the Department of Genetics, is the responsible investigator. He heads a committee of scientists from key Medical School departments and the Stanford Computation Center.

The new computer is being financed by grants from the National Institutes of Health and was planned with funds from the Josiah Macy, Jr. Foundation.

Architect for the project is Milton T. Pflueger of San Francisco.

STANFORD -- A baboon from West Africa may lead scientists to a more effective treatment for human epilepsy, predicts a pharmacologist at Stanford University School of Medicine.

The baboon is a new animal model for human epilepsy, which for the first time has symptoms that both match the disease rather closely and appear to be a species characteristic, reports Dr. Keith F. Killam, associate professor of pharmacology.

Epilepsy, a disease of the nervous system, causes sudden loss of consciousness usually accompanied by convulsive motions of the muscles. It is traditionally studied by inducing seizure activity in laboratory animals either through electrical, chemical or surgical means. However, these approaches have not produced models close enough to the human disease.

The new animal model was accidentally discovered last year by Dr. Killam, his wife, Dr. Eva King Killam, and Dr. Robert Naquet, a specialist in human epilepsy at the Institute of Neurophysiology and Psychophysiology in Marseille, France. Dr. Killam and his wife, while on sabbatical leave from Stanford, were studying the effect of drugs on cats, primates and man in the laboratory of Dr. Naquet.

"As part of our routine testing of the primates," Dr. Killam said, "we flashed light at the animals. Much to our surprise four out of 10 went into convulsions. These were the first cases in which normal animals responded with convulsive seizures to flashing light. From then on our entire course of study changed."

Light sensitivity is characteristic of 60 to 70 percent of all epileptic patients. For about 80 percent of this group, flashing light will trigger a full-blown seizure.

All 10 primates tested were baboons of the Papio papio species from the Casamance region of Senegal. In order to determine whether or not their response to flashing light was related to age, diet, stress or other variables, the investigators decided to examine the animals in their native habitat.

They tested 60 Papio papios in the city of Dakar and 40 in the interior of Senegal. Seventy percent of the animals exhibited a positive response. The response was shown to be independent of site of testing, as well as sex, age, diet, length of capture and degree of handling.

Two other species of monkeys from the same geographic region were also examined and found to be negative.

Returning to Marseille, the scientists tested 40 more Papio papios and compared their responses symptom for symptom to those of epileptic patients. They found a close similarity between brain wave patterns, sleeping records and reactions to certain drugs.

-MORE-

In fact, Dr. Killam noted, the only significant difference was the frequency of light which triggered a seizure. The baboon seizure was triggered at about 25 cycles per second, the human seizure at about 15 cycles per second.

(The research team's findings are reported in the current issue of Epilepsia and will soon appear in the journal of Electroencephalography and Clinical Neurophysiology.)

Dr. Killam and his wife are continuing their studies at Stanford with 10 baboons they brought back from Senegal. Eight of these are Papio papios and two are Papio anubis. Four of the Papio papios show maximum seizure response to flashing light, two show no response and two respond only under certain conditions. The Papio anubis are negative.

The researchers have also tested the chimpanzee population at Holloman Air Force Base in New Mexico and the baboon colony at the Southwest Foundation for Research and Education at San Antonio, Texas. At San Antonio, they examined Papio papios and two other genetic variants of baboon also from West Africa, the Papio anubis and the Papio cynocephalus.

Seven of the 12 Papio papios, two of the 10 Papio anubis and one of the 12 Papio cynocephalus exhibited a positive response. All the chimpanzees were negative.

From these tests, Dr. Killam concludes the Papio papio's sensitivity to light is a species characteristic. He predicts this finding will lead to further research on the genetic transmission of human epilepsy and the possible biochemical differences in the epileptic brain.

"From a pharmacological standpoint," he adds, "the discovery of the new animal model will open a whole new field of drug development."

Most of the time, Dr. Killam explains, a neurologist treats a patient after he has had an attack; he has no way of studying how the first attack might be avoided. "With an animal species that shows such a high percentage of naturally occurring epilepsy, we can now approach this problem experimentally. When we know more about the origin of seizure activity, then the development of new drugs effective in preventing as well as controlling epilepsy should be forthcoming."

Dr. Killam's work is supported by a grant from the National Institute of Mental Health of the U.S. Public Health Service.

Advances in the field of plastic and reconstructive surgery will be the subject of a public lecture next Wednesday night (Dec. 7) at Stanford University School of Medicine.

Dr. Robert A. Chase, professor and executive head of the Department of Surgery, and Dr. Donald R. Laub, instructor in surgery, will speak at 8 p.m. in Room M106 of the Medical School Building. Their talk will be the second in a series of six public lectures on surgery sponsored by the medical school.

Drs. Chase and Laub are primarily interested in surgery as it relates to the rehabilitation of patients both functionally and socially. They will discuss new developments in restorative surgical procedures such as skin grafting, cosmetic surgery, hand surgery, and the reconstruction of missing parts.

They will also describe current research on the transplantation of kidneys in rats, which requires microscopic surgery on tiny blood vessels.

Dr. Chase has been a member of the Stanford faculty and head of the Department of Surgery since 1963. Dr. Laub joined the medical school faculty in July.

Editors: Photos available on request.

Four months ago Mr. and Mrs. William Ward of Bremerton, Wash., were told their 9-year-old daughter Renee would die before Christmas if she did not have a kidney transplant operation.

Today Renee has the hope of leading a normal life. In an operation performed at Palo Alto-Stanford Hospital Center November 29, she received a healthy kidney donated by her mother, Marjorie Ward, 29. Stanford surgeons report Renee's new kidney is functioning normally.

"Many of our friends asked us why we wanted to do this when kidney transplants are still experimental," Mrs. Ward said, "but the operation was the only chance we had. We had no trouble making the decision."

Renee was born with cystinosis, a rare genetic disease that causes crystals to build up in the kidneys and other body tissues. The crystals gradually destroy the kidneys until they eventually stop functioning. The normal life span for victims of the disease is about 10 years.

Renee felt well until last June, her mother said, then she became increasingly tired. She began attending school on a half-day basis in September and finally had to stop in November.

Physicians at the University of Washington School of Medicine sent Renee and her parents to the Palo Alto-Stanford Hospital Center. The University Hospital in Seattle does not perform transplants, although it does treat kidney disease patients with the use of an artificial kidney unit. The unit duplicates the essential blood-cleansing process of healthy kidneys, but it can not remove cystine crystals.

The Stanford surgeons believe Renee's operation will lead to further understanding of the disease itself, in addition to saving her life. Little is known about cystinosis, they said. It may be either a kidney disease or a general metabolic disorder.

The surgeons describe the case as significant because surgery has been used to correct an inborn error in metabolism. This is the first time a kidney transplant has been performed on a patient with cystinosis.

The first obvious improvement after the operation, the surgeons reported, was the complete elimination of photophobia, an inability to tolerate light, caused by the accumulation of cystine crystals in the cornea. Renee no longer squints in the sunshine or cries when the lights are on, the surgeons said.

This was the 12th successful kidney transplant among relatives since the program began at Stanford more than two and a half years ago. Renee is the youngest of the patients to undergo the operation at the Hospital Center. All the patients today lead normal lives.

Renee has two brothers Danny, 10, and Mark, 6, who have been staying with their grandparents Mr. and Mrs. B. L. Miller, 2207 E. 24th, Bremerton. The Wards live at 3021 Nipsic Ave., Bremerton.

STANFORD -- "A New Look at Skin Diseases" will be the subject of the next public lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine Wednesday (Feb. 1).

Dr. Eugene Farber, professor and executive head of the Department of Dermatology, will speak at 8 p.m. in Room M106 of the Medical School Building.

Dr. Farber will describe some of the laboratory techniques used to determine the cause and treatment of skin disease. He will also discuss recent research on hair, blistering disorders of the skin, and the effects of smoking on the skin. Several patients will be present.

This is the first of two lectures on advances in the field of dermatology. Dr. Alvin J. Cox Jr., professor of pathology in the Department of Dermatology, will speak on "The Skin as a Mirror of Internal Disease," February 8.

Dr. Farber has been a member of the Stanford faculty since 1948. He is currently president of the Society for Investigative Dermatology, an international organization of scientists involved in skin research.

"What is it like at the hospital?" a child wants to know.

To answer this question, and to help children anticipate what a hospital stay entails, Palo Alto-Stanford Hospital Center, Palo Alto, California, has begun to make a special illustrated reader part of every pediatric patient's orientation.

Entitled "What is it Like at the Hospital?", the 17-page booklet is being presented to all youngsters admitted to the Hospital Center. Plans are being made to distribute copies to local physicians as well.

Fully-illustrated and set in large, easy-to-read type, the publication offers concrete information about the pediatric ward, its facilities, staff and routine. It answers such questions as "Why Must I Go to the Hospital?", "What Do Children Do All Day in the Hospital?", and "What is it Like to Have an Operation?".

Written by Mrs. Henry Smith of Palo Alto, the booklet is geared to a second-grade reading level. It is also designed to serve as a source of information for parents and a pictorial means of explaining the hospital to pre-school youngsters.

"What is it Like at the Hospital?" came about in connection with the author's preparations for a doctorate in elementary education. While doing graduate work at Stanford University, Mrs. Smith learned that children often have exaggerated notions about the hospital and hospital procedures. She felt that part of the problem might be due to a lack of suitable reading materials, for public libraries have very little access to booklets which can help parents explain the hospital to their children. Furthermore, practically no material pertaining to hospital procedures is written for a child's level of understanding.

Mrs. Smith decided, therefore, to research a booklet which would help familiarize children with the hospital. When her manuscript was completed, she offered it to officials at Palo Alto-Stanford Hospital Center. Working with Mrs. Smith and medical staff pediatricians, the hospital immediately began plans for the booklet's publication.

STANFORD -- Dr. Roy Cohn, professor of surgery and researcher in organ transplantation, will give the next public lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine, Wednesday (Jan. 25).

Dr. Cohn will speak at 8 p.m. in Room M106 of the Medical School Building. He will discuss the historical, social and ethical aspects of kidney transplantation.

According to Dr. Cohn, the success rate of kidney and other transplantations would be increased if certain legal barriers were resolved, particularly in regard to the use of cadaver kidneys and the definition of death.

Stanford surgeons have performed 20 successful kidney transplants between relatives. Kidney transplants are still regarded as highly experimental, although approximately 1,100 have been performed throughout the world.

Dr. Cohn is a 1933 graduate of Stanford medical school. He was appointed to the Stanford faculty in 1938.

Editors: Story released simultaneously by Harvard Medical School.

A Stanford diagnostic radiologist and specialist in the study of the cardiovascular system has been appointed the Philip H. Cook Professor and chairman of the Department of Radiology at Harvard Medical School. He will serve simultaneously as radiologist-in-chief at the Peter Bent Brigham Hospital in Boston.

The radiologist, Dr. Herbert L. Abrams, is currently professor and head of the Division of Diagnostic Radiology at Stanford University School of Medicine.

Dr. Abrams' academic and hospital appointments have been announced respectively by Harvard University and Peter Bent Brigham Hospital. He will assume his new appointments in late summer, 1967.

At Stanford, where he served since 1948, Dr. Abrams is held in high regard by his colleagues as an outstanding diagnostician, a teacher and investigator.

At Harvard, Dr. Abrams will be responsible for both undergraduate and postgraduate teaching in diagnostic radiology.

A native of New York City, Dr. Abrams received the A.B. degree from Cornell University in 1941 and the M.D. degree from the State University of Medicine in New York in 1946. He received his residency training in medicine at Montefiore Hospital in New York, and in radiology at the Stanford University Hospital in San Francisco.

Dr. Abrams is a co-author (with Dr. H.S. Kaplan) of "Angiocardiographic Interpretation of Congenital Heart Disease," a textbook published in 1956, the editor of a two-volume work, "Angiography," published in 1961, and also a co-author (with Dr. S.J. Robinson and Dr. H. S. Kaplan) of "Congenital Heart Disease," published in 1965.

STANFORD -- Heart surgery will be the subject of the next public lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine, Wednesday (Jan. 18).

Dr. Edward J. Hurley, assistant professor of surgery, will speak at 8 p.m. in Room M106 of the Medical School Building.

He will discuss the function of the heart, the use of the heart-lung machine, methods of treating congenital heart disease, and prosthetic valve replacement. He will also show slides and part of a movie on the insertion of an artificial valve.

Dr. Hurley received his M.D. degree from Stanford in 1957. He joined the faculty as an instructor in surgery in 1963 and was promoted to assistant professor in 1964.

In addition to his Stanford appointment, Dr. Hurley is assistant chief of surgery and chief of cardiac and thoracic surgery at the Veterans Administration Hospital. He is an Established Investigator for the American Heart Association and is a member of the board of directors of the Santa Clara County Heart Association.

Two Stanford medical alumni have been named to administrative posts at the Stanford University School of Medicine, Dr. Robert J. Glaser, vice president for medical affairs and dean of the Medical School, announced today.

Dr. Thomas A. Gonda, 45, professor of psychiatry, has been named associate dean, and Dr. Gunther W. Nagel, 72, of San Francisco, emeritus clinical professor of surgery, will serve as director of alumni relations.

Dr. Gonda will have a major responsibility for clinical affairs, including relationships between the Medical School and its affiliated hospitals. He will also be concerned with graduate and postgraduate programs.

Dr. Nagel, first occupant of a newly created post, will work on a part-time basis with the Medical School administration to aid in the continuing development of medical school alumni relationships. Dr. Nagel, who became emeritus in 1959, has continued to be active in medical school and alumni affairs.

Dr. Gonda received the A.B., in 1942, and the M.D., in 1945, from Stanford University. He joined the Stanford faculty in 1953 as a clinical instructor in medicine (neuropsychiatry) and advanced through the academic ranks to become full professor of psychiatry in 1965. From 1958 to 1961, Dr. Gonda was acting head of the Department of Psychiatry, and played an important role in arranging the move of the School of Medicine from San Francisco to the campus in Palo Alto.

He was awarded a special fellowship in 1961 by the National Institutes of Health to do research at Oxford University in England. His special field of interest is the study of alterations in behavior associated with changes in the nervous system. Since 1962, he has been director of the psychiatric residency program at Stanford.

Dr. Nagel received the A.B., in 1917, and the M.D., in 1921, from Stanford University. He was a Fellow at the Mayo Clinic in Rochester, Minnesota for six years and during this time he was awarded an M.S. degree in surgery from the University of Minnesota. He practiced surgery in San Francisco and taught many classes of Stanford medical students from 1929 until his retirement.

Dr. Nagel has published numerous scientific papers dealing with gastrointestinal surgery and most recently a book, THE MAYO LEGACY.

STANFORD -- The function and use of the artificial kidney machine will be the subject of the fourth public lecture on surgery in the series PROGRESS IN MEDICINE at Stanford University School of Medicine, Wednesday (Jan. 11).

Dr. John M. Palmer, assistant professor of surgery and director of the artificial kidney unit at the Palo Alto-Stanford Hospital Center, will speak at 8 p.m. in Room M106 of the Medical School Building.

The artificial kidney is a device that duplicates the continuous blood-cleansing action of healthy kidneys. The machine removes wastes and toxins that normally appear in the bloodstream and could cause death if allowed to accumulate.

Dr. Palmer will describe the history and development of the machine, how it is used, and the economical aspects of its use. He will also show slides on the construction and operation of the machine.

A 1960 graduate of Stanford medical school, Dr. Palmer joined the faculty in 1965 as an instructor in surgery. He was promoted to assistant professor in September 1966.

The artificial kidney unit was donated to the hospital by the Palo Alto-Stanford Hospital Center Auxiliary in March 1966.

STANFORD -- "The Control of Pain" will be the subject of the next public lecture in the series PROGRESS IN MEDICINE at Stanford University School of Medicine Wednesday (March 1).

Dr. Jordan Katz, assistant professor of anesthesia, will speak at 8 p.m. in Room M106 of the Medical School Building.

Dr. Katz will describe three current methods of treating pain: 1) eliminating the source of pain by means of surgery or radiotherapy, 2) stopping pain from reaching the brain with local or regional anesthetics and neurosurgery, and 3) modifying pain once it reaches the brain by using general anesthetics, narcotics, tranquilizers or hypnosis.

He will also discuss the historical development of the control of pain and possibilities for future treatment.

A 1957 graduate of Chicago Medical School, Dr. Katz has been a member of the Stanford faculty since 1963.

STANFORD -- A four-bed pediatric research unit for the study of childhood diseases has been established by Stanford University School of Medicine. Construction of the unit was made possible by a $30,000 gift from The Gillette Company of Boston, Mass.

The pediatric unit is an addition to the medical school's Guggenhime General Clinical Research Center, a 31-bed specialized facility supported by the National Institutes of Health for the intensive study of man and his diseases.

Stanford's clinical research center is the largest and most comprehensive in the United States. It occupies the third floor of the Stanford Pavilion of the Palo Alto-Stanford Hospital Center and includes a special unit for the study of premature infants.

The research center has its own staff, laboratories and facilities to provide the best possible setting for scientists to conduct rigidly controlled studies on carefully selected patients. Faculty members from many departments of the medical school participate in the studies.

Several major diseases will be studied in the new unit, among them:

-- Diabetes; the incidence of diabetes in children is high relative to other metabolic diseases. Researchers are seeking more information about the relationship of the carbohydrate metabolism to insulin secretion in the prediabetic child. The pediatric research unit will provide an opportunity to study the diabetic child before he is given insulin.

-- Hypoglycemia, a condition in which the blood sugar is too low. When hypoglycemia is present in early life, the incidence of mental retardation is high. Investigators hope to develop standard diagnostic procedures that will result in earlier detection of the disease.

-- Convulsive disorders, their origin, control and social consequences.

-- Osteogenesis imperfecta, a disease characterized by brittle bones that fracture easily, leading to deformities and progressive disability in the child. Fluoride therapy may help these children, but its use must be critically evaluated, and the necessary observations can only be made in a controlled research environment.

-- Hurler's Syndrome, an inherited disorder characterized by mental retardation, enlargement of the head and body organs, and early death. Researchers intend to study the relationship between vitamin C and the synthesis of mucopolysaccharides, chemical substances produced in abnormally large amounts in children with the disease.

-- Anemia; children with severe iron deficiency anemia lose excessive protein by their excreta. Investigators wish to examine the role of nutrition as it applies to this disease and others. The special diet kitchen in the pediatric unit will be an essential working tool for them.

-- Congenital heart disease in children.

-- Liver disease; basic scientists are developing more accurate laboratory methods for analyzing enzymes in the blood. These methods will enable more exact correlation of enzyme blood levels with liver disease than is presently possible.

STANFORD -- The Stanford Medical Faculty Wives organization has established a scholarship fund for a medical student at Stanford University School of Medicine.

Mrs. Hadley Kirkman, president of the group, recently presented a $500 check to Dr. LeRoy A. Pesch, associate dean. The money represents an accumulation of dues over the six year period of the group's existence.

"We wanted to do something more to help the medical school," Mrs. Kirkman said. "We hope the gift will grow in following years and be of lasting assistance."

The group was organized in 1961 "to promote school-wide interdepartmental acquaintance" and "to assist in medical school affairs as needed." Wives of all members of the full-time faculty and the clinical faculty are invited to join. The group has about 300 active members.

Mrs. Kirkman is the wife of Dr. Hadley Kirkman, professor emeritus of anatomy. She has assisted her husband for several years as a laboratory research technician in the Department of Anatomy.

STANFORD -- The common view that one form of cancer--Hodgkin's disease--is incurable and hopeless is statistically unwarranted and should be vigorously challenged, two leading cancer investigators believe.

Drs. Henry S. Kaplan and Saul A. Rosenberg of the Stanford University School of Medicine, have challenged the pessimistic views that, they feel, stem from outdated experience with "crude diagnostic methods and primitive radiation equipment."

Proponents of these "deeply pessimistic" views, based on observations in the first half of this century, have held that Hodgkin's disease is incurable, according to the Stanford researchers, because it recurs in treated areas, spreads in a disconcertingly unpredictable manner, seems systemically distributed from its inception, and instances of apparent cure may be discounted as errors in diagnosis.

Hodgkin's disease is malignancy of lymph nodes, part of an important infection-fighting system in the body. The disease kills about 3,500 persons in the United States each year. Several groups, including the National Cancer Institute, the American Cancer Society, and individual scientists have attempted to make known the possibilities of prompt and proper treatment for this disease.

In recent speeches and publications, Drs. Kaplan and Rosenberg have repeatedly stated their belief that the death rate from Hodgkin's disease could probably be cut sharply if more physicians and their patients knew what they should about this form of cancer. And they add that many failures in treating the disease with radiation are due to the "low energy x-ray beams" used, with which it is difficult or impossible to deliver curative doses.

"Recent analysis of data from a number of radiotherapeutic centers," Drs. Kaplan and Rosenberg said, "reveals a striking inverse relationship between recurrence rate and radiotherapeutic dose." The pooled data of various studies have shown that x-ray therapy with low dosage levels offers no chance of cure except among those few patients who have very early, localized disease.

-more-

As radiation dose increases the recurrence rate falls rapidly and approaches almost zero at a dose level of 4,000 rads (the rad is a standard unit of radiation dose). This high dosage may be localized to avoid vital structures, they explained, and can be given safely if delivered in divided doses.

According to the calculations of the Stanford investigators, 80 to 90 percent of patients with only a few lymph nodes affected by Hodgkin's disease "can be offered apparently permanent cure" with intensive radiation.

The Stanford investigators dispute the general impression that Hodgkin's disease spreads randomly and unpredictably. If this were true, treated patients with "apparently localized disease" would eventually show activity in other sites, and long term survival free of disease would be extremely rare.

But Drs. Kaplan and Rosenberg have found that a high proportion of patients survive five years after intensive radiotherapy for localized disease, and many survive 10 or 15 years or longer. Most survivors had no recurrence after the initial treatment, and several patients who later died of other disease, at autopsy had no trace of Hodgkin's disease in the treated sites or elsewhere.

The investigators emphasize that effective treatment of Hodgkin's disease "is inextricably linked to the meticulous and thorough evaluation of the extent of disease in each patient prior to treatment. Unless all areas of disease that can possibly be detected by present methods are identified and treated intensively, it is not reasonable to expect treatment to be successful."

The best results, they said, can be expected only when decisions regarding diagnostic evaluation and treatment in each case are reached jointly by the patient's physician, an experienced radiotherapist, and an internist qualified in cancer chemotherapy.

"Under such circumstances," Drs. Kaplan and Rosenberg said, "a very considerable proportion of all patients with regionally localized disease can be offered a chance of permanent cure with radiotherapy, and patients with more advanced disease can be offered prolonged periods of comfortable and productive life with use of drugs and radiotherapy."

They added that Hodgkin's disease will continue to challenge researchers as it has in the past. Information from such varied sources as epidemiological studies, routine application of the newest diagnostic techniques, controlled clinical studies, and immunological research gives promise that a better understanding of Hodgkin's disease will lead to further improvements in cure rates.

Dr. David M. Kaplan, director of the psychiatric social service division of the University of Colorado Medical Center, has been appointed associate professor of preventive medicine and head of the division of clinical social work at the Stanford University School of Medicine.

He will also serve as director of social service for the Palo Alto-Stanford Hospital Center.

Dr. Kaplan, 48, will join the Stanford faculty July 1. He succeeds Dr. Daniel O'Keefe who resigned last year to become dean of the School of Social Work at Michigan State University.

According to Dr. Robert J. Glaser, vice president for medical affairs and dean of the school of medicine, the appointment follows a comprehensive study of Stanford's needs in the area of social service. As a result of the study, the division of clinical social work has been reorganized as part of the Department of Preventive Medicine.

In his new position, Dr. Kaplan will have responsibility for expanding the contribution of social work to patient care, teaching and research. He will supervise a group of about 30 professional personnel.

Dr. Kaplan has been a member of the faculty and director of the social service division of the Department of Psychiatry at the University of Colorado Medical Center since 1962. He is also a faculty member at the University of Denver School of Social Work.

For the past three years he has been co-director of a five-year National Institute of Mental Health project entitled "The Family Concept and Comprehensive Psychiatric Care."

Prior to his appointment at the University of Colorado, Dr. Kaplan was an instructor in mental health and an associate in social work at the Harvard School of Public Health. He has had four years experience as a caseworker in New York City and Cleveland, Ohio.

Dr. Kaplan received his B.S. degree in 1939 from the College of the City of New York, his M.S. degree in 1947 from the New York School of Social Work, and his Ph.D. in 1961 from the University of Minnesota.

By using an experimental drug, two Stanford University researchers have pinpointed a specific brain center which regulates the production of the male sex hormones.

The drug, Cyproterone, a potent antimale hormone, normally suppresses masculine sexual function when it circulates in the blood and does not reach the brain in large amounts. But when it was implanted inside the brain of male rats, the drug stimulated sexual function by increasing secretion of gonadotropic hormones.

The researchers found that a particular brain center in the hypothalamus called the "median eminence" is specifically involved in activating the mechanisms that produce gonadotropin secretion.

The researchers, George J. Bloch, a graduate student in physiology, and Dr. Julian M. Davidson, assistant professor of physiology at Stanford University School of Medicine, reported their findings in the current issue of SCIENCE, the journal of the American Association for the Advancement of Science.

Normally, when there is a deficiency of the male hormone, the pituitary produces gonadotropic hormone which, in turn, stimulates the testes to produce male hormone.

The receptor area in the organism responsible for stimulating gonadotropin release from the pituitary gland in response to male hormone deficiency was not precisely known. By implanting the drug in the form of slowly dissolving crystals inside the brain of male rats, the Stanford researchers observed that it triggered a chain of processes ending in increased male hormone production and enlargement of the animals' testes and prostates.

This meant that the drug prevented access of the male hormone to receptors in the brain area where the drug had been implanted. The brain, in turn, sensing the apparent decrease in male hormone, activated the mechanism that stimulates the male reproductive system.

The researchers said that in earlier experiments they implanted crystals of male hormone in the brain's median eminence. Sensing the presence of too much of the male hormone, the brain gave signals to shut down male hormone production.

More recent studies on implantation of Cyproterone in the pituitary gland showed no effects on sexual function of the animal. Thus the pituitary gland itself is not sensitive to variations in sex hormone levels in the blood but depends on signals from the receptor in the brain, the researchers said.

The research is supported by a grant from the National Institute of Child Health and Human Development of the National Institutes of Health.

STANFORD -- Dr. Grant Fletcher, assistant professor of anesthesia, will discuss "What's New in Inhalation Therapy," at Stanford University School of Medicine Wednesday (Feb. 15).

Dr. Fletcher will speak at 8 p.m. in Room M106 of the Medical School Building. He will describe new methods of treatment for patients with acute respiratory problems.

A 1946 graduate of Stanford University School of Medicine, Dr. Fletcher has been a member of the Stanford faculty since 1963. He also serves as medical director for the inhalation therapy service of the Palo Alto-Stanford Hospital Center.

The program is the first of two sponsored by the Department of Anesthesia as part of Stanford's series of public lectures on PROGRESS IN MEDICINE. Dr. Jordan Katz, assistant professor of anesthesia, will speak on "The Control of Pain," March 1.

STANFORD -- "The Skin as a Mirror of Internal Disease" will be the subject of the next public lecture in the PROGRESS IN MEDICINE series at Stanford University School of Medicine, Wednesday (Feb. 8).

Dr. Alvin J. Cox Jr., professor of pathology in the Department of Dermatology, and Dr. William M. Gould, acting instructor in dermatology, will speak at 8 p.m. in Room M106 of the Medical School Building.

The two physicians will explain how changes in the skin may reflect disease or a drug reaction in the body. Symptoms of the body's general response to disease are often first recognized in the skin.

As a pathologist in the Department of Dermatology, Dr. Cox helps analyze skin disease by performing laboratory tests and conducting research on skin problems. Dr. Gould, as a practicing dermatologist, works with the patient to treat the disease.

Dr. Cox is a 1931 graduate of the Stanford University School of Medicine and has been a member of the faculty since 1933. Dr. Gould, also chief of the dermatology service at the Veterans Administration Hospital, joined the Stanford faculty in 1964.

Editors: Copies of STANFORD TODAY are available on request.

STANFORD -- New organs for old will be commonplace some day, but researchers working to perfect surgical techniques also must hurdle such human factors as public sentiment and legal terminology.

Such is the opinion of Dr. Roy Cohn, professor of surgery at the Stanford University School of Medicine.

Writing in the current issue of STANFORD TODAY, the university's quarterly magazine, Dr. Cohn says that human organs--most effectively the kidney--can be transplanted. But the problems which now loom largest are economic, legal, sociological, ethical, and moral in nature.

"The success rate in kidney and other transplantation would be increased if we had a new definition of death, permitting the removal of organs at a more optimal time," Dr. Cohn wrote. "Physicians would prefer that the cessation of brain function for 48 hours (as indicated by an absence of waves in the electroencephalogram), rather than cessation of the heart beat, be considered as death. It is possible for the heart to go on beating for days after the brain has passed beyond possible recovery."

Dr. Cohn explained that transplantation is best done with tissue from living donors, but obviously this is not always possible. So far methods of organ preservation have yielded meager results. It is not possible to maintain a "bank" except for the inert structural type of organ such as the cornea, bone, and arteries.

Surgeons have used cadavers as a source of kidneys, but experience shows they must be used within a short time, maximally about three hours, or they will not function. "The success rate where this source has been used the most is about 40 percent," Dr. Cohn wrote. "This success rate could be increased were it not for the legal barrier to obtaining the cadaver kidney promptly."

-more-

He said that although statutes vary in different states, the practical situation is that permission of the next of kin must be obtained after death before an organ can be removed from the body. This can be true if the deceased has willed the organ.

Dr. Cohn cited the case of a man who was offered to the Stanford Medical Center as a donor by his family. The man had been accidentally shot in the head and his brain was destroyed. "The uncertainties of the law in regard to the right of the family to make this offer as well as the responsibilities of the physicians in accepting this patient whose heart was beating normally, whose breathing had been taken over by a mechanical respirator, and whose kidneys were functioning normally were so indefinite that those priceless kidneys could not be used," he said. The patient was pronounced dead several days later.

Another problem concerned with kidney transplantation is cost. Hospitalization alone costs somewhere between $6,000 and $30,000 depending upon complications, Dr. Cohn pointed out. This figure does not include medical fees and expenses for drugs which are needed after the patient leaves the hospital.

Patients at Stanford are supported by grants from the National Institutes of Health which also cover the cost of the enormous number of observations before and after the operation.

There are sociological and psychiatric problems concerned with the future of the donor in kidney operations. Life insurance statistics indicate that a healthy person with one kidney has a very small decrease in life expectancy compared to the same individual with two kidneys. "Yet the donor as a person cannot be compared in terms of statistics," Dr. Cohn wrote. "The fact remains that he is giving away something which someday he may need just as desperately as the intended recipient. There are problems here for the psychiatrist, not only in dealing with the donor but also with his family."

Is transplantation justified on any basis? "There are those who feel that the whole procedure is morally wrong," Dr. Cohn said. "As others in the medical profession besides myself have pointed out, more than ever before in the present stage of our knowledge, the referring physician and the surgeon must look to their respective consciences and heed the words of Matthew, "'Whatsoever ye would that men should do to you, do ye even so unto them.'"

Dr. Cohn said the fact that 3,500 kidney patients die every year for lack of treatment indicates the enormous amount of work that lies ahead. "But the time may be shorter than we think," he added. "Surgeons are far advanced in the techniques of transplantation, and work is being actively pressed in many laboratories toward a reliable method of circumventing the rejection process."

He expressed hope that many others besides physicians--lawyers, sociologists, theologians--will be able to give an increasing amount of study to their aspects of the problem.

STANFORD -- The untrained but "properly supervised" volunteer is a useful answer to the shortage of mental health workers, a Stanford psychiatrist believes.

Addressing the annual meeting of the American Orthopsychiatric Association in Washington, D.C. (March 22), Dr. John F. Belz, assistant professor of psychiatry, described a six-year experimental program with volunteers in the Peninsula Children's Center, a day treatment center for emotionally disturbed children, in Menlo Park.

The Peninsula Children's Center is used as a training and research facility for the Stanford University psychiatry and psychology departments. It accommodates 18 children aged 4 to 18 years. Dr. Belz serves as medical director.

The center's small staff--a child psychiatrist, the executive director, a psychiatric social worker, four teachers and a music therapist--considered the use of volunteers as a temporary expedient, Dr. Belz said.

"But now the volunteers, one for each of the children, constitute a highly integrated purposeful part of the treatment program."

The volunteers may be young college girls or women with grown children. They maintain a regular schedule, coming in once a week.

"The major objective is for the volunteers to relate to the patients in a personal way," Dr. Belz explained. "Emphasis is placed on helping a child enter the world of reality. The volunteer may utilize paints, blocks, music or other media."

It is equally important, he added, for the volunteer to be able to sit with a child through rages, walk with him or her, or in any other acceptable way lend strength, warmth and affection.

The trial period for volunteers usually lasts one month. When a new volunteer becomes intrigued with a particular child, he begins to seek guidance from the staff member primarily responsible for the child, as well as from the parents' therapist. Volunteers also participate in record keeping and staff conferences in a deliberate intermingling with the permanent staff.

"Parents are astounded that people who don't really have to, spend time with their disturbed child," Dr. Belz noted. "Mothers and fathers are thus helped to look at their children differently."

Since volunteers work only one day a week, they also maintain "a freshness and a high level of interest that we doubt could be sustained by the same group of workers who meet the same children day after day," he said.

"The volunteers provide an economical source of compassionate child caretakers. And in some instances, college-age volunteers have eventually decided to enter the mental health field."

STANFORD -- Dr. Henry G. Kunkel, noted immunologist, will deliver the twentieth course of Herzstein Medical Lectures sponsored by the medical schools of Stanford University and the University of California.

Dr. Kunkel, professor at Rockefeller University and senior physician at Rockefeller Hospital in New York, will speak on March 27, 29 and 31 at 8 p.m. in the Medical Sciences Auditorium of the University of California San Francisco Medical Center.

His three lectures are: Monday, March 27, "Recent Developments in the Field of Immune Globulins;" Wednesday, March 29, "Mechanisms of Renal Injury in Systemic Lupus Erythematosus," and Friday, March 31, "Immunological Aspects of Rheumatoid Arthritis." The lectures are open to the public as well as to the medical profession.

Dr. Kunkel is known for his outstanding contributions to the understanding of serum protein metabolism and for his recent work on human antibodies and immunological aspects of disease.

The Herzstein Medical Lectures were established in 1929 by the late Dr. Morris Herzstein of San Francisco.

STANFORD -- The Stanford University School of Medicine today received approval from the University Board of Trustees to develop a master plan to build and finance new facilities for several basic science departments and a new hospital and ambulatory care center.

Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine, termed the action "as a major step in moving forward toward meeting the School's critical educational needs and alleviating the serious bed shortage that exists in the community."

He indicated that the first step in implementing the Trustees' action would be the appointment of a team of experts to develop the master plan and a program to achieve the necessary funding. The timetable for completion of the new facilities will be about four years.

"To achieve its full potential in patient care, teaching and research, the School of Medicine needs a University hospital with an adequate number of beds and the necessary supporting administrative organization," Dr. Glaser said. "It also needs an an ambulatory care center to provide more effectively for patient care and teaching in the field of comprehensive medicine."

The new Basic Science Building will house the departments of Anatomy, Physiology and Medical Microbiology, none of which were provided for in the Medical Center when it was constructed in 1959. These departments are now in scattered locations on the campus. The Department of Pathology, as well as others occupying space in the present Center, will have additional facilities in the proposed Basic Sciences addition, Dr. Glaser said.

"These basic science departments are vital to medical education," Dr. Glaser said, "and none of them presently has adequate facilities."

The present Palo Alto-Stanford Hospital is jointly owned by the City and the University. Dr. Glaser said it would be necessary at a later date for the University to enter into negotiations altering the present joint ownership agreement with the City of Palo Alto.

-more-

During the past year, Stanford University and the City of Palo Alto have engaged in negotiations to change the present unwieldy ownership structure.

Dr. Glaser emphasized that the School of Medicine is not lessening its community responsibility but rather is moving to develop facilities to enable the School to contribute more effectively to the education of the physicians and medical scientists necessary to meet the community's and the nation's health needs. He repeated an earlier statement that members of the Medical School's volunteer faculty, many of whom are now on the Palo Alto medical staff, would continue to participate in the Stanford educational and patient care programs.

The development of an ambulatory care center as part of the proposed new University hospital complex has been termed by Dr. Glaser as "one of the most important challenges before us." In contrast to acute and limited care beds in the new hospital, the ambulatory care center will provide for comprehensive care for patients who do not need to be hospitalized. Such a unit will function in place of the traditional outpatient clinic, and also will make possible new innovations in the education of physicians.

"Care in such a center should serve better the patient's needs and should make for significant economies," Dr. Glaser said. "It will also enhance our programs for the education of outstanding physicians for the coming decade."

There are about 200 beds now available to the Stanford University School of Medicine in the 437-bed Hospital. These beds, now fully occupied, according to Dr. Glaser, are inadequate to meet the School's present patient care, education and research needs. The School of Medicine has stated it needs 400 to 500 beds.

In July, 1966, at the request of the City Council, Stanford submitted a proposal to purchase Palo Alto's interest in the Hospital and offered to make available additional land contiguous to the Hoover Pavilion (former Palo Alto Hospital) for the expansion of a community hospital on that site.

The Council rejected the Stanford proposal. Consequently, the University announced it would plan new hospital facilities and would "in due course, create the Stanford University Hospital as an independent unit, both administratively and functionally."

STANFORD -- "Babies, Seals and Milk" will be the subject of a public lecture at Stanford University School of Medicine Wednesday (March 22).

Dr. Philip Sunshine, assistant professor of pediatrics, will speak at 8 p.m. in Room M106 of the Medical School Building.

He will describe the problem of lactose malabsorption, an abnormality in which the body lacks a certain enzyme responsible for the absorption of the primary sugar in milk. Children with lactose malabsorption suffer from diarrhea and poor weight gain.

By studying sea lion pups, which also lack the necessary enzyme, scientists are now able to more clearly understand and diagnose the problem.

Dr. Sunshine will show slides, including pictures of the sea lions he studied on the Coronado Islands off the coast of Baja California.

This is the first of four lectures on pediatrics in the medical school's PROGRESS IN MEDICINE series. The others are scheduled as follows:

APRIL 5: "German Measles in Pregnancy and Its Effect on the Newborn," by Dr. Jordan Wilbur, assistant professor of pediatrics.

APRIL 12: "Diseases of Metabolism in Children," by Dr. Robert E. Greenberg, associate professor of pediatrics.

APRIL 19: "Pediatrics in a University Setting," by Dr. Norman Kretchmer, professor and executive head of the Department of Pediatrics.

STANFORD -- Dr. Charles H. Stuart-Harris, professor of medicine at the University of Sheffield, England, has been named the second James J. Waring Visiting Professor at Stanford University School of Medicine.

The professorship, awarded each year to a distinguished physician in the field of chest diseases, was established by the Francis S. North Foundation of Chicago. It honors the late Dr. James J. Waring, professor of medicine at the University of Colorado and chief of medicine at Colorado General Hospital for more than 20 years.

Those named to the professorship spend equal time at Stanford and the University of Colorado School of Medicine.

Professor Stuart-Harris will be in residence at Stanford from March 20 to 25. He will conduct ward rounds, work with medical students and house staff, and be available for staff consultations.

He will give a lecture Thursday (March 23) at 5 p.m. on "The Role of Infection in Chronic Respiratory Disease" in Room M106 of the Medical School Building. He will also participate in a day-long postgraduate symposium on lung tumors beginning at 8:30 a.m. Saturday (March 25) in Room M104. Both events are open to physicians and medical students in the community.

In addition to his position on the faculty of the University of Sheffield, Professor Stuart-Harris is a consultant physician to the United Sheffield Hospitals. He has been a Foulerton Research Fellow of the Royal Society, a research fellow at the Rockefeller Institute for Medical Research and a visiting professor of medicine at Albany Medical College, Albany, New York. He received his M.D. degree at the University of London in 1934.

Professor Stuart-Harris is the author of numerous publications and articles, chiefly relating to the fields of chest disease and virology.

STANFORD -- "The Laser in the Treatment of Eye Diseases" will be the subject of a public lecture at Stanford University School of Medicine Wednesday (March 15) at 8 p.m.

Dr. H. Christian Zweng, clinical assistant professor of surgery, will speak in Room M106 of the Medical School Building. His lecture is part of the medical school's PROGRESS IN MEDICINE series.

Dr. Zweng is presently studying the biological effects of laser energy on eye tissue in an attempt to determine its usefulness in the treatment and prevention of eye diseases that lead to blindness. He is a member of a research team composed of scientists from the medical school and Stanford Research Institute.

In addition to his position on Stanford's clinical faculty, Dr. Zweng is an eye physician and surgeon at the Palo Alto Medical Clinic.

A television camera is placed in the premature nursery to demonstrate a procedure to a group of students in a nearby classroom.

A professor video tapes his lecture and in the privacy of his office, analyzes his performance as a teacher.

A researcher uses a camera to record the responses of an animal in a test situation.

A psychiatrist televises a patient interview to aid him in diagnosis.

These are some of the many ways closed circuit television is revolutionizing medical teaching, research and patient care throughout the country. Since last fall, Stanford University School of Medicine has been experimenting with a new $57,000 television system, which is now ready for full operation.

Six permanently mounted 25-inch television monitors have been installed in two classrooms in the medical school. In addition, a single 25-inch monitor on a rolling stand can be used in any of the rooms in the Stanford Medical Center.

The remainder of the television system includes three cameras, two connected to a large console and a small one for auxiliary use; a variety of lenses; a two-way audio system, and a video tape recorder with an audio channel.

To date, the medical school's television equipment has primarily been used for three types of programs:

-- A "live" remote demonstration in which a program is televised some place in the medical center and simultaneously relayed to the monitors in a classroom. Several weeks ago students in a classroom were able to watch researchers in the Respiratory Function Laboratory obtain information on the respiratory processes of a young man riding a bicycle. The two-way audio system allowed questions and discussions between the laboratory personnel and the class.

-more-

-- A "live" demonstration in the classroom. A group of 150 students recently watched a televised demonstration of a kidney operation on a rat. A magnified view of the operation was projected onto the 25-inch monitors, enabling the last five rows to see as well as those standing two feet away.

-- A demonstration for future use. Dr. Keith Killam, associate professor of pharmacology, has taped a program explaining a laboratory assignment to students. The assignment involves an experiment to test the effect of certain drugs on the brain of a cat. The program was televised in two separate laboratories. In one, Dr. Killam uses diagrams and charts to explain the experiment, and in the other, the animal is shown in the actual test situation. Using a special effects generator, it was possible to obtain split screen and cornering effects, allowing the charts and test situation to be televised simultaneously.

Tapes such as Dr. Killam's will conserve time for both faculty and students. The professor will no longer have to explain assignments several times to different classes, and the tapes can be edited or updated for use the following year. The student will eventually be able to check out tapes from a library for preview or review of class assignments and demonstrations.

The purchase of the closed circuit television system was initiated by Dr. Lewis Aronow, associate professor of pharmacology, and financed by gifts to the medical school.

STANFORD -- South Vietnam faces serious health problems intensified by a shortage of physicians and supplies, inadequate hospital facilities and the tragedy of war, according to a specialist in tropical diseases who spent two months in the besieged Mekong Delta.

Dr. Mark T. Hoekenga said that the hospital at Can Tho where he served as a civilian doctor has 450 beds, but often as many as 650 patients. And this hospital is typical of other provincial hospitals in South Vietnam.

"I found that two to three patients to a bed was a common occurrence," Dr. Hoekenga said. "The wards were hot and crowded, frequently ripe with odors of sweat and urine. Open sewers sometimes added to the pungency.

"Except in the intensive care and postoperative wards, patients slept on sleeping mats placed on top of board frames. They wore their own clothes, the ones they were wearing when they were injured or took sick. Family members stayed with the patients to assist in feeding and nursing them, sleeping on or under the bed as space and time permitted."

Dr. Hoekenga, a Stanford Medical School alumnus and scientific director of William S. Merrell Company in Cincinnati, went to Can Tho under the American Medical Association's program "Volunteer Physicians for Vietnam." His report appears in the current issue of STANFORD M.D., the quarterly magazine of the Stanford Medical Alumni Association.

"Our days as physicians were long," Dr. Hoekenga wrote. "Speaking a little French, but more often using Vietnamese interpreters, I saw 50 to 80 or more outpatients and attended an equal number of hospitalized ones.

"All of the usual temperate climate diseases are prevalent in Vietnam--the respiratory, cardiovascular, gastrointestinal, and genitourinary ailments that one sees everywhere in the world. But, in addition, tuberculosis, infectious hepatitis, and typhoid fever are rampant. Cholera, malaria and parasites are fairly common, and even bubonic plague and leprosy and other exotic diseases are encountered.

-more-

"Often during my tour of duty, essential supplies were short. The equipment was inadequate. Always there was the horror and sorrow of the war around us, the evidence of vicious (Viet Cong) attacks on civilians with small arms fire, mortars and Claymore mines, accounting for 40 percent of the surgery done on civilians.

"Plague is a serious health problem in Vietnam. A total of 4,453 cases with 253 deaths have been reported by the Ministry of Health in 1965 (the latest statistics available). Because of the high rat population and a lack of flea control, many locations in the highlands as well as in Saigon will continue to be involved."

Dr. Hoekenga said that fleas in Vietnam are resistant to DDT and warned that transportation of such resistant fleas in exported cereal grains could have serious international consequences.

Although the United States and other free nations have moved rapidly to fill the physician shortage and have improved the medical care of South Vietnamese, the ratio of physicians to population remains a most unfavorable one, Dr. Hoekenga reported. Of the 1,100 Vietnamese physicians, some 700 are in the army, and approximately 100 more are not in practice because of political activity. This leaves 300 physicians to treat 15,000,000 civilians in the country.

Dr. Hoekenga related the story of two Viet Cong prisoners in his care. Both of them were handcuffed to their beds, and a guard was posted outside the door. "What a paradox!" Dr. Hoekenga wrote, "Yesterday our side tried to kill them. Today, as doctors, we try to save their lives. It is particularly strange to see how unimpressed the other patients and their families are. One might think that a patriotic nationalist would try to knife them, or at least cut the intravenous infusion tube. But they all seem to have lived with war so long that this, too, they take in stride."

Now and then there is a sign of human warmth and kindness--of hope for the future. "Last night," Dr. Hoekenga wrote, "Father Campbell, the Catholic Chaplain for the IV Corps region, came back to chat awhile. He started to talk about a project that obviously is dear to his heart--the providing of shelter and school for a large group of orphans 10 to 15 years old who shift for themselves under lean-tos or on shelves near the river. He isn't having much success with shelter and school, but meanwhile is keeping them clean and fed.

"Each evening he goes down to the river with a fresh bar of soap and throws it to the boys. Only those who lather thoroughly, rinse, lather, and rinse again will get a ration of food that he then doles out."

Dr. Hoekenga said no one here in Can Tho has any answers to the problem in Vietnam. "The only certain aspect is that being on the scene makes one think deeply about the significance of it all."

"My present feeling is based on two premises," Dr. Hoekenga wrote. "The first is that international communism is an evil thing that threatens our own democratic system of government and must therefore be fought. The second premise is that overwhelming majority of intelligent South Vietnamese do want to help in resisting it. If these premises are true, we have no alternative but to get on with the job with vigor and dispatch."

Cancer research at the Stanford University School of Medicine received a substantial boost today in the form of a $400,000 gift from a California businessman.

Sam G. Willson of Oakland, a retired contractor, made the gift to establish the Jack and Lulu Willson Fund for Cancer Research in honor of his parents.

"It is my fond hope," Willson said, "that by providing some assistance to those who seek more knowledge about cancer, medical science may develop methods of prevention and control of the disease."

In announcing the gift, Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, commented: "The Jack and Lulu Willson Fund for Cancer Research will stand in the years to come as an example of the generosity and dedication of a fine citizen to the development of medical knowledge. Nothing would please us more than for the Willson Fund to be the means whereby a new and important breakthrough in the understanding of cancer can be attained."

The Stanford University School of Medicine conducts cancer research on a broad front. It encompasses research ranging from the development of new and more effective techniques in radiation treatment to basic studies which may lead to a better understanding of what causes rapid and unregulated cell growth in cancer. An increasing knowledge of the biological behavior of cancer cells and of the action of radiation on cells may lead to techniques by which cancer may be more easily and selectively eradicated.

Income from the Willson Fund will be applied to the support of investigators whose studies are not funded by Federal grants, Dr. Glaser said.

Willson comes from a pioneering California family. His father, Alfred John Willson, who was known affectionately as "Jack," came to California from Fordham, England, as a young man. For more than 40 years he was associated with the Hercules Powder Company at Pinole, Calif. until his death in 1929.

Willson's mother, Lulu Nicholl Willson, was the daughter of John Nicholl, who came to California from New York in the 1850's and was one of the first settlers and founders of the City of Richmond on the San Francisco Bay.

STANFORD -- Scientists at the Stanford University School of Medicine and the Stanford Research Institute in Menlo Park, California, are taking a new look at the remarkable laser to determine its usefulness in the treatment and prevention of eye diseases that lead to blindness.

Aided by a $246,000 grant from the National Institutes of Health to the School of Medicine, the researchers are studying the biological effects of laser energy on eye tissue and are making plans for developing a laser that would be "clinically superior" to conventional photocoagulators.

The researchers plan to study several applications, among them:

* the effects of different laser wavelengths on eye tissue through high-speed cinematography (up to 9,000 frames per second) and microscopic studies of eye tissues.

* the amount of light energy needed to produce curative results on eye tissue.

* laser treatment of eye tumors.

* the effects of laser treatment in certain eye complications of diabetes.

* use of the laser to burn a hole in the iris of the eye to restore vision. The iris, which makes the pupil and controls the amount of light entering the eye, is often closed or seriously deformed as a result of disease.

* laser treatment of glaucoma, a condition responsible for a large proportion of blindness today. Glaucoma is a disease manifested by an increase of pressure inside the eye. The pressure is caused because the blood that comes into the eye to nourish it is blocked. A laser, according to the investigators, could be used to destroy the tissue that blocks the outflow and perhaps prevent rapid degeneration of vision.

The research team from the School of Medicine includes Dr. H. Christian Zweng, clinical assistant professor of surgery, Dr. Milton Flocks, clinical associate professor of surgery, Dr. Robert Peabody, senior resident in ophthalmology, and Dr. Robert C. Rosan, assistant professor of pathology.

-more-

The engineering team responsible for laser instrumentation includes Dr. Richard C. Honey, Dr. Arthur Vassiliades, Norman Peppers and Zev Pressman of the Electromagnetic Techniques Laboratory at the Stanford Research Institute.

"The potential value of lasers has been recognized," Drs. Zweng and Flocks commented. "However, their use has been limited to the treatment of certain retinal defects. The best way of applying laser radiation to eye disorders is still imperfectly understood. Studies to date indicate that lasers probably will prove to be clinically superior to conventional photocoagulators."

Unlike the laser, the old-fashioned photocoagulator which is presently used by ophthalmologists to treat eye diseases utilizes visible light from a xenon arc. It is bulky and must remain in a fixed position when in use. It produces large scars compared to the pin point lesions produced by the laser. And often anesthesia is used to prevent the patient from blinking his eyes when they are exposed for long periods to the bright light.

In the laser, light output is monochromatic, coherent and extremely intense. These unique properties make the laser an ideal source for photocoagulation since high heat intensity can be obtained with a low amount of energy, the researchers said. The heat can be focused directly to the tissue being treated and minimize damage to adjacent tissues.

It was in the summer of 1963 that ophthalmologists Zweng and Flocks beamed a laser light from a small hand-held device into the eye of a patient who was losing vision because of a detached retina in one eye. The beam passed through transparent tissue and liquid in front of the eye, reached the retina in back and spot-welded it back in place.

The treatment was over so fast that the patient did not even feel it. No anesthesia was needed and no hospitalization either.

Before applying the laser on human patients, Drs. Zweng and Flocks studied its use on rabbits, cats, and monkeys. From these studies, the ophthalmologists determined the energy levels that could be used safely on patients. They subsequently treated 175 patients with a variety of retinal defects with no known complications.

This early research took two years and was carried on cooperatively by the Stanford University School of Medicine, the Palo Alto Medical Research Foundation and Optics Technology, Inc., of Palo Alto which developed the laser instrument. Other firms, the American Optical Company of Southbridge, Mass., and Keeler Optical Company in London, are producing laser photocoagulators commercially.

Drs. Zweng and Flocks emphasized that they have no interest in overseeing the construction of such a clinical instrument on a production basis. However, doing the research necessary to determine what such instrument should be is one of the purposes of the research effort. As practicing ophthalmologists, they would like to see the laser photocoagulator become available to practitioners. They hope that their research will be published and will contribute to the eventual creation of a usable device.

STANFORD -- Dr. J. Garrott Allen, internationally known for his research on blood and hepatitis, will give a public lecture at Stanford University School of Medicine Wednesday (March 8) at 8 p.m.

He will speak on "Delusion, Confusion and the Single Transfusion" in Room M106 of the Medical School Building. The lecture is part of the medical school's PROGRESS IN MEDICINE series.

Dr. Allen will discuss the seriousness of serum hepatitis, caused by blood transfusions from carriers of the virus, and possibilities for preventing the disease.

He believes the most practical methods for reducing the hazard of serum hepatitis are to limit the use of blood by giving fewer transfusions, and by excluding, if possible, all high-risk donors.

A 1938 graduate of Harvard Medical School, Dr. Allen has been a professor of surgery at Stanford since 1959.

STANFORD -- The Stanford University School of Medicine and four other schools that have made sweeping curricular changes in recent years are today's leaders in medical education, according to a member of the Royal Commission reviewing the future of medical training in Great Britain.

"Yale, Stanford, U.C.L.A., and Duke universities are, in my opinion, blazing a trail which the rest of us are likely to follow sooner or later," said Dr. G. Morris Carstairs, professor and head of the department of psychiatry at the University of Edinburgh. Another institution that has made recent curriculum reforms in medicine is the University of Indiana.

Dr. Carstairs came to the United States in 1961 on a fact-finding mission and visited more than a dozen medical schools noted for their quality. He revisited several of them in intervening years and in 1966, when he was a fellow at the Center for Advanced Study in the Behavioral Sciences at Stanford.

His findings are presented in the current issue of PHAROS, the quarterly magazine of Alpha Omega Alpha, the honor medical society.

The five medical schools have had, in Dr. Carstairs' words, "the courage to realize that medical education in the future must be less comprehensive and more diversified.

"Elective study serves two ends: it enables students to go more deeply into some of the sciences related to medicine, and it teaches them techniques of self-education which will be of value to them throughout their careers."

Dr. Carstairs said that while some British medical schools have made some "strenuous efforts at curricular change, none of these changes has been as bold as those which one finds in Yale, Stanford, the University of California at Los Angeles, Duke and Indiana universities."

Yale, Stanford and Duke, Dr. Carstairs noted, are private institutions with a staff-pupil ratio unattainable by ordinary schools. Indiana and U.C.L.A. are state-supported.

"What they all have in common," he said, "is a willingness to sacrifice completeness of coverage, both in the preclinical and clinical years, in favor of stimulating the students' comprehension of the scientific approach to each different aspect of medicine, and showing the students how to find out things for themselves."

-more-

For several years, Yale has allowed its students one whole semester of elective study. It is now proposed to double this, so that one year out of four will be spent in approved elective work.

The Stanford University School of Medicine has a five-year program, during which 40 percent of the students' time (two years) is devoted to elective study. The new curriculum's success at Stanford is demonstrated by the performance of students in national examinations. For three consecutive years the classes that took the first and second part of the tests (covering their knowledge of basic sciences and clinical medicine) have attained grades averaging above the honors score.

Stanford has also been in the forefront in designing and maintaining laboratories for integrated teaching in the basic medical sciences. It was in the vanguard of medical schools in establishing a department of genetics, and was successful in achieving an unusually effective integration between the humanities and sciences and the pre-clinical sciences.

The new curriculum at the University of California at Los Angeles has involved an overall reduction of teaching time by 10 percent in order to provide generous periods of elective study, according to Dr. Carstairs. Duke University, whose example was followed in 1967 by Indiana University, has made the radical change of compressing the preliminary preclinical instruction into one-year course, followed by a 16-month stretch of clinical and applied-science teaching and clerkship; after this students can choose electives from a range of alternatives in medical science, basic sciences or in clinical fields.

"I have come away from this exposure to the ferment of curriculum reform which is taking place in American medicine today with the conviction that most of our teaching, on both sides of the Atlantic, is still subject to the basic criticisms of the Goodenough Report," Dr. Carstairs said. "It is overloaded with factual content and does not sufficiently encourage the students to think for themselves."

(The Goodenough committee was established by the British government during World War II to review existing medical schools and postwar needs.)

"In the intervening quarter century," Dr. Carstairs said "the rate of accretion of scientific knowledge has enormously increased, so that these criticisms have still greater force today than in 1944."

STANFORD -- Dr. Donald C. Harrison, assistant professor of medicine, has been appointed head of the division of cardiology at Stanford University School of Medicine.

The appointment was announced by Dr. Robert J. Glaser, vice president for medical affairs and dean of the school of medicine, and became effective February 1.

Dr. Harrison succeeds Dr. Herbert N. Hultgren who is on sabbatical leave at Dartmouth Medical School until September, when he will resume his teaching responsibilities at Stanford.

A member of the Stanford faculty since 1964, Dr. Harrison has been a research fellow at Harvard Medical School and a clinical and research associate at the National Heart Institute in Bethesda, Md. He received his B.S. degree in 1954 from Birmingham Southern College and his M.D. degree in 1958 from the Medical College of Alabama.

Dr. Harrison is interested in clinical and basic research in cardiac pharmacology, particularly relating to antiarrhythmic drugs, which are given to patients after a heart attack or heart surgery to restore normal cardiac rhythm, and adrenergic drugs, which block part of the nervous system as it controls the heart.

He is presently a member of the board of directors of the Santa Clara County Heart Association.

Dr. Harrison and his wife, Laura, and their three children live at 151 Mountain View Ave., Los Altos.

Stanford University today appointed a newspaper publisher and civic leader to the board of directors of the Palo Alto-Stanford Hospital Center.

Joseph Cannon Houghteling, 43, of Atherton, will fill the unexpired term of Eric M. Stanford who resigned for personal reasons. Stanford, an executive vice-president and director of I. Magnin and Co., was appointed in 1963 to fill the unexpired term of James Duprau and was reappointed to a full three-year term the following year. Stanford's term would have expired in December, 1967.

In announcing the new appointment, President J. E. Wallace Sterling expressed the University's "abundant and abiding thanks" for Stanford's services on the Hospital Board.

Houghteling is president of the corporations which publish the Los Gatos Times-Saratoga Observer, the Gilroy Evening Dispatch, the Pleasanton Times, and Nevada County Nugget. From 1956 to 1965 he was editor and publisher of the Sunnyvale Daily Standard and allied publications. He is also a director of the Diablo Press of Berkeley.

He has served as chairman of the California Park Commission, vice-chairman of the San Francisco Bay Study Commission, and was a member of the California Highway Commission from 1964 to 1967.

Houghteling was born in San Francisco and is a graduate of Yale University.

He has been active in the Democratic Party and has served on county, state and numerous committees. He was a delegate to the Democratic national conventions in 1956 and 1960, and was active in various campaigns in organizational and finance roles.

Houghteling lives with his three daughters Anne, Elizabeth and Mary at 5 Fenwood Drive in Atherton. His wife, the former Frances Fisher, died in 1963.

STANFORD -- Dr. Edmond D. Butler Jr., chief resident in urology at Santa Clara County General Hospital, has been awarded a $7,500 research fellowship by the Bank of America-Giannini Foundation. The fellowship will begin July 1.

Dr. Butler plans to use the award at Stanford University School of Medicine, where he has been appointed an instructor in surgery for the 1967-68 academic year.

His research project involves the use of computer techniques in the study of urinary infection, bladder physiology and kidney function.

The fellowship program was established in 1945 by the late A.P. Giannini, founder of Bank of America. The purpose of the program is "to support individual projects of unusual originality in medical research." The awards are intended to help young post-doctoral investigators in the early stages of their careers.

The fellowships are granted annually to six California doctors. The other recipients this year are from the University of California School of Medicine in San Francisco, UCLA School of Medicine and Loma Linda University School of Medicine.

STANFORD -- "The Emphysema Epidemic...A Population at Increased Risk?" will be the subject of a public lecture at Stanford University School of Medicine Wednesday (April 26).

Dr. Karlman Wasserman, assistant professor of medicine, will speak at 8 p.m. in Room M106 of the Medical School Building. His lecture is part of the medical school's PROGRESS IN MEDICINE series.

Emphysema is a disorder of the respiratory system that causes shortness of breath with activity. A recent report from the National Health Survey indicates that the number of new cases of emphysema has been doubling every three years since 1950.

Dr. Wasserman will discuss possible explanations for the increasing occurrence of the disease, including improved diagnostic techniques and the effects of air pollution. He will also describe some of the experimental studies conducted on emphysema.

In addition to his position on the Stanford faculty, Dr. Wasserman is director of the Respiratory Function Laboratory for the Palo Alto-Stanford Hospital Center.

STANFORD -- The Stanford University School of Medicine today received a $59,273 grant from the Office of Economic Opportunity to conduct a full-scale Upward Bound program this summer.

The program will accommodate a maximum of 46 students for eight weeks during the summer and one day a week during the coming academic year. Funds from the program will support salaries for high school teachers, tutor-counselors and a small coordinating staff. Faculty members from the Stanford University School of Medicine and five assistants will teach the science and laboratory courses.

The program also will pay a $10 stipend per student a week during the summer and $10 a month during the academic year. A morning snack, lunch and dinner will be provided five days a week on the campus.

The program will differ this year in that it does not provide for overnight housing for students on campus. "Ideally, we support the residence program," said Dr. LeRoy A. Pesch, associate dean. "We have been forced to balance the advantages of a residence program for fewer students than 40 against a nonresidence program for 46, and feel that the latter choice is far preferable. A 15 percent increase is much better than losing ground in the number of students reached."

Dr. Pesch said that a rented campus residence will provide a center for the students, a place for relaxation and meetings, tutoring and special interest activities. "Thus the decision not to house the students overnight will not deprive them of any essential aspect of the Upward Bound experience," he added.

Stanford's original Upward Bound program began in the summer of 1965 with 20 students who attended classes on a nonresidential basis. Last year it was expanded to 40 students who lived in University residences.

-more-

University faculty members at first had hoped to double the program size to 80 students, then scaled their aims down to 60 students when they were informed that federal support would not be increased as much as originally planned. Finally, they voted to withdraw from the program because of inadequate financial support.

The School of Medicine, however, whose faculty members have carried on a limited program parallel to Upward Bound, funded by the National Science Foundation, offered as an alternative to continue the high school student program under OEO auspices. They said the program was successful, pointing to the many students who were motivated to continue their education in top colleges and universities.

Dr. Pesch said the purpose of the program is to broaden the student's awareness of the opportunities and challenges of science and medicine. "We hope to provide sufficient incentive, guidance and help to enable highly able students, who for economic, cultural or educational reasons would not otherwise do so, prepare and qualify for a college and professional education."

The students will be selected from San Mateo County high schools within commuting distance with preference given to those achieving below expectations as indicated by school counselors and their teachers. The selection procedure will guarantee an interracial composition of the student group.

The teaching will include courses in English, writing, mathematics, science, and laboratory demonstrations to stimulate students toward professional careers in the sciences and humanities.

The Upward Bound program has received some opposition from members of the Community Action Council in East Palo Alto. Their demands consist of nine points contained in a "Petition by Upward Bound Students." Stanford has agreed to the first six in principle.

The other points in the petition--a demand for a $50 stipend per student a month, a compulsory donation of faculty time, control over appointments to the teaching faculty by the local advisory committee, and a designation of a board of directors to guide Upward Bound policy, have been ruled out by Richard Frost, director of Upward Bound in Washington, D.C. In a letter to Mrs. Everlyn Wallace, chairman of the Community Action Council, Frost wrote the demands were in violation of the program's guidelines.

XERO COPY XERO COPY XERO COPY XERO COPY

"The (Stanford) proposal received here was judged, on program terms, to be a good one," Frost wrote. "The site-visit reports we have from consultants who inspected the program in the summer and academic year of 1966-67 are, on the whole good reports. No program is perfect anywhere in America. Stanford's compared to the hundreds elsewhere, is a good one."

STANFORD -- William G. Hayden, fourth year medical student at Stanford University School of Medicine, has received an award from the Roche pharmaceutical company as "an outstanding student of medicine."

The Roche Award, an engraved gold wrist watch, is presented each year to a student who has completed three years of medical school at Stanford. According to Dr. LeRoy A. Pesch, associate dean, Hayden was selected for the award on the basis of his academic excellence and research.

Hayden has been conducting research on the mechanism of abnormal heart rhythm known as atrial flutter. His findings will appear in the May issue of CIRCULATION RESEARCH, the monthly publication of the American Heart Association. He plans to specialize in cardiovascular surgery.

Hayden is vice president of the Stanford Medical Student Association and president of the fourth year class. He received his A.B. degree from Stanford in 1963.

STANFORD -- Advances in the treatment of child health problems will be discussed in a public lecture at Stanford University School of Medicine Wednesday (April 19) at 8 p.m.

Dr. Norman Kretchmer, professor and executive head of the Department of Pediatrics, will speak on "Pediatrics in a University Setting" in Room M106 of the Medical School Building. He will focus on Stanford's approach to pediatrics and the relationship of the department to the community.

Dr. Kretchmer will summarize current research and patient care programs in the areas of mental retardation, sensory defects, chronic disease, behavioral problems and the major causes of death of children.

This is the last of four public lectures on pediatrics sponsored by the medical school as part of its PROGRESS IN MEDICINE series. On April 26 Dr. Karlman Wasserman, assistant professor of medicine, will speak on "The Emphysema Epidemic: A Population at Increased Risk?"

STANFORD -- Dr. Samuel L. Kountz, 36, assistant professor of surgery at Stanford University School of Medicine, has received a $21,390 grant from the Lederle Medical Faculty Awards Program.

The award will be used to supplement his salary and professional expenses over a period of three years.

Dr. Kountz has played an active role in the kidney transplantation program at Stanford. Under the award he plans to continue his investigations to detect early kidney rejection and to pinpoint the exact time large doses of immunosuppressive drugs must be given to reverse a rejection. He hopes to extend his studies to methods of tissue typing and to apply this to organ transplantation.

In addition to his research, Dr. Kountz is a full-time member of the medical school's teaching faculty and is involved in the development of a curriculum for medical students in surgery.

The Lederle Medical Faculty Awards are supported by Lederle Laboratories, a pharmaceutical firm, which is a division of American Cyanamid Company with headquarters in Pearl River, New York.

Lederle Laboratories allocates $250,000 annually for grants to approximately a dozen young medical educators who give promise of continuing in full-time teaching and medical research.

Dr. Kountz obtained his M.D. at the University of Arkansas School of Medicine in 1958. He served his internship and residency at Stanford, and became a member of the faculty in 1965.

He received the Young Investigator's Award from the American College of Cardiology in 1964 and was a Fulbright Professor to the United Arab Republic for three months in 1966.

Dr. Kountz and his wife, Grace, and their two sons live at 2091 Camino de las Robles in Menlo Park.

STANFORD -- The screening of newborn babies to detect genetic diseases will be discussed in a public lecture at Stanford University School of Medicine Wednesday (April 12) at 8 p.m.

Dr. Robert E. Greenberg, associate professor of pediatrics, will speak on "Diseases of Metabolism in Children" in Room M106 of the Medical School Building. The lecture is part of the medical school's PROGRESS IN MEDICINE series.

Dr. Greenberg will focus on the disease phenylketonuria (PKU), a rare inborn error of metabolism that causes mental retardation. He will discuss the significance of recent California legislation calling for PKU blood tests of all newborn babies.

Next Wednesday evening (April 19) Dr. Norman Kretchmer, professor and executive head of the Department of Pediatrics, will present the final lecture in a series of five on pediatrics. His topic will be "Pediatrics in a University Setting."

STANFORD -- The seventh annual Stanford Medical Student Day will be held Saturday, April 8, in the Physics Lecture Hall on the Stanford campus.

The day-long event, beginning at 9 a.m., will feature the second Lowell A. Rantz Memorial Lecture. Dr. Robert W. Berliner, director of intramural research for the National Heart Institute of the National Institutes of Health in Bethesda, Md., will speak on "The Regulation of Sodium Excretion."

The lecture was established in memory of the late Dr. Lowell A. Rantz who was associate dean, professor of medicine and head of the Division of Infectious Diseases. He was also an alumnus of the medical school.

In addition to the lecture, six students selected by a student-faculty committee will present original research papers. Each of the six participants will receive an award from the Stanford Medical Alumni Association.

Following the papers, Dr. Berliner will lead a clinical pathological conference. The program will conclude with a reception at the University Club of Palo Alto.

Student Day is sponsored by the Stanford Medical Student Association and the Stanford Medical Alumni Association. Conference chairman is Kai Haber, fourth year medical student.

STANFORD -- "German Measles in Pregnancy and Its Effect on the Newborn" will be the subject of a public lecture at Stanford University School of Medicine Wednesday (April 5).

Dr. Jordan R. Wilbur, assistant professor of pediatrics, will speak at 8 p.m. in Room M106 of the Medical School Building. His lecture is part of the medical school's PROGRESS IN MEDICINE series.

German measles contracted during pregnancy can retard the development of the newborn child and cause physical deformities, especially in the heart. It can also lead to cataracts, hearing loss, skin hemorrhage, mental retardation and chronic problems with other internal organs.

Dr. Wilbur is a 1961 graduate of the Stanford medical school and has been a member of the faculty since 1965.

STANFORD -- Dr. Robert M. Shelton, of Pasadena, is the new president of the Stanford Medical Alumni Association, and Dr. William H. Clark, of Palo Alto, is its new president-elect.

Dr. Shelton, a specialist in internal medicine, succeeds Dr. Henry Gibbons III, of San Francisco. He will serve as president of the Association through June, 1968. Dr. Shelton received the A.B. from Pomona College in 1932, and the M.D. from the Stanford University School of Medicine in 1937. He is past president of the Pasadena Medical Society and past chairman of the medical economics committee of the California Medical Association. He is a director and member of the executive committee of Blue Cross of Southern California and a member of the visiting committee of the Stanford University School of Medicine.

Dr. Clark is also an internist and a partner in the Palo Alto Medical Clinic. He is also a clinical associate professor of medicine in the Stanford University School of Medicine, and a Palo Alto City Councilman. Dr. Clark ~~is a graduate of the University of California and of Stanford, Class of 1944.~~ holds an A.B from Stanford and an M.D. from Stanford University School of Medicine, Class 1944.

Others elected to the board of governors of the alumni association are Dr. Robert E. Berner, of Palo Alto, and Winston W. Benner, of Oakland. Dr. David A. Rytand, of Atherton, Bloomfield professor of medicine at the Stanford University School of Medicine, was re-elected secretary-treasurer.

FOR A.M. RELEASE THURSDAY, JUNE 1, 1967

STANFORD -- The Stanford University School of Medicine has received a $500,000 grant from the Commonwealth Fund of New York to initiate planning for a new hospital and ambulatory care center and to advance fundamental reforms in the patterns of hospital services and education in the health professions.

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, said the Commonwealth Fund's generous grant will assist Stanford to undertake "a creative enterprise that will encompass physically a new concept in hospital construction and the delivery of comprehensive health services."

He said the planning studies to be undertaken by the School of Medicine are directed toward a solution of the widespread national problem of the escalating scale of hospital costs, fast becoming a foremost issue in health financing.

A chief factor in the problem is the relative inefficiency, in terms of the health-care return on the dollars expended, of prevailing hospital designs and patterns of utilizing staff, space, and equipment. Stanford is taking advantage of its need for a new hospital to plan a facility that will assure a superior standard of care and, at the same time, incorporate features to limit costs.

The planning project will extend for a period of two years. The Commonwealth Fund's grant will be used chiefly toward the costs of a small planning staff and consultants in such fields as architectural design, management systems, computer technology, and automation processes and equipment. These experts will collaborate with the medical faculty and scholars in relevant nonmedical departments and schools of the University--for example, economics, sociology, and engineering--in the design of both the physical structure and operational system of the new hospital and ambulatory care center.

The proposed health facilities are part of the Medical School's master plan now under development, which also envisions construction of a new basic science building for the departments of Anatomy, Physiology, Pathology, and Medical Microbiology.

Dr. Glaser said the planning studies will constitute a fundamental examination of the hospital as a service system, with emphasis on the application of modern managerial techniques and engineering technology in achieving optimum use of available resources. The studies will seek to determine how staff should be trained and deployed to serve the hospital patient-care responsibilities most advantageously, what aspects can be automated, and what design concepts would be most suitable.

-more-

"The operating patterns of the nation's large hospitals, with multi-million-dollar budgets, have not been subjected to the kind of scrutiny that is employed in industry," Dr. Glaser said. "For example, most hospitals have very large nonprofessional staffs, with high turnover rates. As a result extraordinarily high costs are incurred. No multi-million-dollar enterprise in the competitive world would prosper under such circumstances."

Dr. Glaser said the new hospital design will embody two objectives. First, facilities will be related to the specific stage of care required by the patient, from those needing minimal supervision to patients requiring round-the-clock intensive care. In contrast, most hospital patients now tend to be treated in facilities that assume identical seriousness of illness and involve the same cost to the patient and the hospital. Second, a comprehensive-care service, stressing ambulatory, or outpatient care, will be an integral part of this multi-stage hospital concept.

"Nationwide, there is a serious lack of innovative planning for hospitals," Dr. Glaser commented. "We need to show the way for vitalizing obsolete hospitals and to articulate a program for research and demonstration projects that would help find new and improved ways of organizing and delivering health services. This would raise the quality of care, increase the efficiency of operation and render hospitals more suitable as centers for research and training."

Dr. Glaser said that Stanford's new plans will make it necessary for the City and the University, joint owners of the present 437-bed Palo Alto-Stanford Hospital, to alter their present relationships. "The Medical School's diverse research, education, and patient care needs have made all the more apparent the necessity of an independent University-controlled hospital."

Stanford has about 200 beds in the present hospital. The School of Medicine has stated it needs 400 to 500 beds to carry out its mission.

STANFORD -- "New Treatments for Infertility" will be the subject of a public lecture at Stanford University School of Medicine Wednesday (May 31).

Dr. Emmet J. Lamb, assistant professor of gynecology and obstetrics, will speak at 8 p.m. in Room M106 of the Medical School Building.

Dr. Lamb will discuss recent advances in the treatment of infertility, particularly the use of drugs to stimulate ovulation, new techniques for diagnosing and treating the blockage of Fallopian tubes resulting from infection, and the practical application of tests for immunological causes of infertility.

A member of the Stanford faculty since 1963, Dr. Lamb also is director of the Infertility and Gynecologic Endocrinology Clinic at the medical center.

This is the final lecture in the medical school's PROGRESS IN MEDICINE series for the 1966-67 academic year. The series will be resumed next fall.

STANFORD -- Almost two months ago Cecelia Bebek, a San Jose secretary, suffered shortness of breath, fatigue, lack of sleep and other serious symptoms of heart disease.

Today, thanks to the miracle of open-heart surgery and a heart valve from an unknown benefactor, Miss Bebek is on her way to recovery and normal life.

The new aortic valve (the valve through which blood emerges to supply her body) comes from a young man who died in an automobile accident. Miss Bebek will never know his name. Nor will she know his parents who let their son's aortic valve be used to save her life.

Her heart problem started a year ago following an infection. Miss Bebek had been born with an aortic valve deformity. The infection damaged her deformed valve and brought on her difficulties.

On March 31, Miss Bebek was wheeled into the operating room of the Palo Alto-Stanford Hospital Center for open-heart surgery. There, while a heart-lung machine took over the functions of her heart and lungs, a Stanford Medical School surgical team replaced her damaged valve with the young man's.

Miss Bebek has a tremendous enthusiasm for life. Since her own life was laid on the line last March, she said that she feels each day is a gift to be lived to the fullest. Her breathing is normal now, her appetite has returned, and she has gained weight.

Miss Bebek owes her life in part to a new system which allows Stanford surgeons to obtain fresh cadaver valves for transplantation in heart patients.

Operated like a "bank" such as is now used for storage of eye corneas, it makes fresh cadaver valves available <u>where</u> they are needed and <u>when</u> they are needed, according to Dr. Norman E. Shumway, professor and head of the division of cardiovascular surgery. It also permits researchers to improve methods of heart valve storage.

-more-

It works this way: the admitting office, nursing service, and emergency room at the Center are alerted to notify the cardiac surgeon on duty when a patient dies. The surgeon immediately contacts the patient's family and secures permission to use the heart valves for transplant surgery. Valves from cancer patients or from patients who have died of infectious diseases are not suitable. So far many families have responded favorably.

The new procedure has these advantages, Dr. Shumway said. Fresh valves are available, a heart patient does not have to wait two or three weeks for the transplant operation, and the procedure is much less expensive. Fresh valves--obtained no later than 12 hours after death and less than five days old--are vital to the success of a cadaver valve transplant.

"Presently much of this valuable tissue is wasted because the public is not aware of the progress made in the field of open-heart surgery," Dr. Shumway commented. "If relatives of patients who die knew they could make a heart valve donation, hundreds of other patients suffering from incurable heart disease could be saved."

He said results from animal studies over a two-year period, and a series of valve replacements on 12 heart patients at the Palo Alto-Stanford Hospital Center indicate "fresh cadaver valves are very satisfactory for the replacement of diseased heart valves."

Although at present these transplants are limited to the aortic valve, like Miss Bebek's operation, laboratory evidence favors cadaver valves for mitral valve replacement as well, he added. This work, however, is not yet ready for human application.

The transplanted valves apparently are "privileged tissue," like corneas, so that a valve homograft is not promptly rejected as are other transplants. "The patient needs no special drugs to suppress the immune reaction or to prevent blood clotting," Dr. Shumway said. "Fresh valves are also superior to preserved valve tissue due to the significant incidence of leakage around the latter after human implantation.

"The valves are impressive in their ability to function for extended periods and show no apparent fatigue or disintegration," he added.

Residents in the area who desire to will their heart valves or to make a heart valve donation from a deceased relative may contact the Division of Cardiovascular Surgery at the Stanford University School of Medicine, telephone 321-1200, Ext. 5771.

STANFORD -- "Emergency Psychiatry and Suicide Prevention" will be the topic of a public lecture at Stanford University School of Medicine Wednesday (May 24).

Dr. Alfred E. Weisz, chief resident in psychiatry, will speak at 8 p.m. in Room M106 of the Medical School Building. His lecture is part of the medical school's PROGRESS IN MEDICINE series.

Dr. Weisz will discuss the extent of the suicide problem in the United States and will trace the historical development of suicide prevention programs, focusing on current research and training projects.

He will also discuss religious and legal views of suicide and the significance of various sociological and psychological factors affecting suicide potential.

Dr. Weisz is in his third year of residency and is presently serving as acting instructor in psychiatry.

STANFORD -- Skiers and hikers ascending from such low-lying areas as San Francisco Bay to 9,000-foot or higher mountains can suffer fatal altitude sickness if they ignore the warning symptoms, a Stanford cardiologist said today.

Knowledge of symptoms and remedies can be the difference between a disaster and a pleasurable outing, according to Dr. Herbert N. Hultgren, professor of medicine at the Stanford University School of Medicine.

He presented his warning in an article titled "Lessons from High Altitude" in the May issue of STANFORD M.D., the quarterly magazine of the Stanford Medical Alumni Association.

Dr. Hultgren based his article on research that he and his colleagues have been conducting since 1958 in the Peruvian mining community of La Oroya, 12,200 feet high in the Andes.

The Peru research project, he said, has revealed that altitude sickness generally involves acute pulmonary edema rather than heart malfunction. Pulmonary edema is the movement of fluid from the blood into the air sacs of the lungs. The fluid acts like a salt-water and egg-white mixture. It froths when the patient breathes and quickly "drowns" him.

The symptoms of pulmonary edema--a persistent cough, shortness of breath after the slightest exertion, a gurgling noise in the chest, coughing up of blood-streaked sputum, and vomiting--usually do not appear until six to 36 hours after arrival in a high-altitude area, Dr. Hultgren wrote.

These signs resemble those of pneumonia, but without chills or fever. When the danger signals occur, the patient should be quickly brought to lower altitude and given absolute bed rest with oxygen continuously administered. Recovery is usually complete in three days.

-MORE-

"A similar clinical picture is seen in mountaineers," Dr. Hultgren wrote, "but because of the frequent unavailabililty of oxygen and the long time required for evacuation to a lower altitude, the edema may be severe and frequently fatal. Many deaths previously ascribed to pneumonia may have been high-altitude pulmonary edema, uncomplicated by infection.

Acute high-altitude pulmonary edema occurs most frequently in persons who travel within a day or two to elevations of over 9,000 feet, Dr. Hultgren explained. But acclimatized mountain residents who visit a low altitude for one to two weeks and then return to a higher elevation also seem susceptible.

Since this condition can be fatal, Dr. Hultgren offers these words of advice:

· methods of prevention and treatment should be emphasized to anyone traveling to an altitude of over 9,000 feet. Mountaineers should be especially aware of the syndrome because of the frequent lack of available oxygen and difficulty of prompt removal of the victim to a lower elevation.

· acclimatized persons returning to high elevations and persons who have had previous attacks of altitude sickness should be informed of preventive measures and methods of treatment.

· adequate time should be taken in gradual ascent to permit full acclimatization. After arrival at a high altitude area, a period of rest and inactivity for one to two days should be observed.

· cough, shortness of breath, noisy breathing or blood-streaked sputum are indications of prompt medical attention.

· all mountaineering parties bivouacking above 10,000 feet should have available emergency oxygen and appropriate tools and spare parts should be provided to utilize additional oxygen if dropped by plane.

Dr. Hultgren said that further studies of the causes of high-altitude pulmonary edema are being pursued in the cardiology laboratory at Stanford since it is apparent that it may have many features in common with pulmonary edema occurring in other conditions of heart disease.

STANFORD -- More than 400 medical alumni and their wives will attend the Stanford Medical Alumni-Faculty Reunion Friday (May 19) at the Stanford University School of Medicine.

The theme of the day-long program will be "A New Look at an Old Art," featuring aspects of the medical school's teaching program in the morning, and topics of broad clinical interest in the afternoon.

Speakers at the morning sessions will be Dr. Robert Chase, professor and head of the Department of Surgery; Dr. Halsted R. Holman, Berthold and Belle N. Guggenhime professor of medicine and head of the Department of Medicine; Dr. Arthur Kornberg, Nobel Prize winning biochemist and head of the Department of Biochemistry; and Dr. Norman Kretchmer, professor and head of the Department of Pediatrics. The sessions will begin at 9:45 a.m. in Room M106 of the Medical School Building.

A special program for wives will feature a panel discussion on "Drugs and the College Student" at 9:45 a.m. in Tresidder Memorial Union. Panelists are Joel Smith, associate provost and dean of students; Dr. Avram Goldstein, professor and executive head of the Department of Pharmacology; Dr. B. Davie Napier, dean of the chapel and professor of religion; William Keogh, former associate dean of the School of Law; and James A. Paulsen, psychiatrist-in-chief, Cowell Student Health Center.

Afternoon program for wives includes a bus tour of new building additions on the campus and a guided tour of the Leland Stanford Jr. Museum by Dr. Lorenz Eitner, professor of art history and executive head of the Department of Art and Architecture.

Medical alumni day will be concluded with reunions for the classes of 1917, 1922, 1927, 1932, 1937, 1942, 1947, 1952, 1957, and 1962.

STANFORD -- Scientists can now detect tiny traces of metals in a single human cell or part of a cell by making it go up in a puff of smoke.

It is done through a new application of the laser--an optical device that produces a thin beam of light of tremendously high energy.

The laser beam is focused through a microscope on a minute piece of tissue. The tissue is vaporized at a temperature of about 18,000 degrees over a period of a few millionths of a second.

The light from the minute brilliant cloud, which is a hundredth of an inch high, is made up of many wavelengths that produce a spectrum of the cell's chemical composition. The intensity of the color at each wavelength depends on the quantity of a particular metal present in the original sample. The intensity is measured by a very sensitive photoelectric tube attached to a spectograph. The electric current from the phototube can be recorded directly in terms of metal amount in the sample and compared with samples of known metal content.

The new laser application is being developed at the Stanford University School of Medicine by Dr. David Glick, professor of pathology, and Drs. Edwin S. Beatrice and I. Harding-Barlow, research associates. Their work is supported by the National Institutes of Health.

In recent experiments, the Stanford research team has succeeded in detecting metals like iron and zinc in single human red and white blood cells, sperm cells, and liver and kidney cells.

Metals necessary for human life as well as those which could possibly be dangerous to health can now be identified as a result of the new technique, the investigators said. Among more than a dozen of these essential minerals or "trace metals" in the human body are iron, zinc, and copper.

-MORE-

"The human body contains enough of these metals to make a two-inch iron, a one-inch zinc and one-fourth of an inch copper nail," the researchers explained. "But since the importance of these metals lies in their use within the cell, we are confronted with two problems. First, the size of the average human cell is about 1/20 the diameter of a human hair or the size of a single pollen grain. Second, the trace metals constitute only a millionth or, more often, a billionth part of the entire cell.

"The problem then is one of measuring a few million trillionths of an ounce of metal in a sample the size of a very fine pollen grain."

Until now the same analysis done with conventional test-tube methods was difficult or required considerable time for each element in the cell, the researchers emphasized.

Although the present research is aimed at studying chemical substances in body tissues that are of interest to biologists and medical scientists, Dr. Glick foresees a future application of the technique in clinical laboratories.

"Single drops of blood or other body fluids (instead of the large quantities now required) could be used to furnish rapid, simultaneous analysis of a number of elements," Dr. Glick said. "The advantage of requiring only a one-drop sample (actually, less would suffice) from each patient, the ability to store the dried samples indefinitely, the ease of mailing such samples, and the fact that laser analysis could be automated and the data computerized--all offer considerable possibilities."

#####

(Mailed May 15, 1967)

Drs. David Glick (left), Edwin S. Beatrice, and I. Harding-Barlow of Stanford's department of pathology, display laser apparatus used to detect minute quantities of metals in a human cell or even a portion of a cell. With a single burst of intense light, tissue under microscope at left is turned into a puff of smoke. Light brilliant cloud is analyzed by spectograph at right, which separates the light into its many colors or wavelengths. Intensity of color at each wavelength reveals quantity of a particular metal in original sample which can be measured by sensitive equipment.

STANFORD -- The use of drugs in the prevention and treatment of heart attacks will be the subject of a public lecture at Stanford University School of Medicine Wednesday (May 17) at 8 p.m.

Dr. Donald C. Harrison, assistant professor of medicine and chief of the Division of Cardiology, will speak on "New Drugs for Survival After a Heart Attack" in Room M106 of the Medical School Building. The lecture is part of the medical school's PROGRESS IN MEDICINE series.

Dr. Harrison will discuss the various kinds of heart attacks, their symptoms and causes. He will specifically describe his research on the effects of lidocaine and propranolol on acute cardiac arrhythmia, a disturbance of the normal heart beat, which frequently accompanies a heart attack.

According to Dr. Harrison, 40 per cent of all early deaths from heart attacks are caused by acute arrhythmias. He believes the majority of these deaths, about 200,000 per year, can be prevented with early detection of the arrhythmias and the use of drugs.

In addition to his position on the Stanford faculty, Dr. Harrison is chief of cardiology for the Palo Alto-Stanford Hospital Center. He also is a member of the board of directors of the Santa Clara County Heart Association.

STANFORD -- Women and their diseases will be the subject of a public lecture at Stanford University School of Medicine Wednesday (May 10).

Dr. John McLean Morris, visiting professor of gynecology and obstetrics, will speak at 8 p.m. in Room M106 of the Medical School Building. His lecture, entitled "Women," is part of the medical school's PROGRESS IN MEDICINE series.

Dr. Morris will discuss the historical origins of the specialty of gynecology and current research on the detection and treatment of cancer in women. He will also cover the biological and psychological aspects of sex differentiation, human reproduction and the effects of contraception on sexual behavior.

Professor of gynecology at Yale University School of Medicine, Dr. Morris was appointed a visiting professor at Stanford for the 1966-67 academic year.

The following three lectures will conclude the PROGRESS IN MEDICINE series for the academic year. The series will be resumed next fall.

MAY 17: "New Drugs for Survival After a Heart Attack," by Dr. Donald C. Harrison, assistant professor of medicine and chief of the Division of Cardiology.

MAY 24: "Emergency Psychiatry and Suicide Prevention," by Dr. Alfred E. Weisz, chief resident in psychiatry.

MAY 31: "New Treatments for Infertility," by Dr. Emmet J. Lamb, assistant professor of gynecology and obstetrics.

STANFORD -- Two fourth year medical students at Stanford University School of Medicine have been elected to Alpha Omega Alpha, the national honor medical society.

The two students are Ronald Levy and William G. Hayden.

Earlier this year, six fifth year students were also elected to the society. They are: M. Jan Dray, Samuel D. Hellis, Edgar K. Marcuse, Richard G. Offutt, William M. Palmer and Peter W. Wright.

Medical students are elected to Alpha Omega Alpha on the basis of scholarship and potential leadership. To qualify, they must be fourth or fifth year students in the upper 25 per cent of their class.

Students and their parents' names and addresses are listed below:

CALIF., DOWNEY - Richard Offutt, Mr. and Mrs. W.V. Offutt, 8523 E. 11th St.

EL CAJON - William Palmer, Mr. and Mrs. Morris H. Palmer, 1721 Vista Way

MENLO PARK - Samuel Hellis, Mr. and Mrs. H. Dean Hellis, 294 Waverley, Apt. 4

PALO ALTO - Ronald Levy, Mr. and Mrs. Herman H. Levy, 420 Hale

CONN., WILTON - Peter Wright, Mr. and Mrs. Robert Wright, 489 Danbury Rd.

N.Y., N.Y. - Edgar Marcuse, Mr. and Mrs. J.E. Marcuse, 1125 Park Ave.

PENN., DUSHORE - William Hayden, nephew of Mrs. Agnes Hochberg (parents deceased)

WASH., SEATTLE - M. Jan Dray, Mr. and Mrs. M.H. Dray, 11541 Third N.W.

STANFORD -- "Man's Disorientation in Space: from hangovers to...SCUBA diving" will be the subject of a public lecture at Stanford University School of Medicine Wednesday (May 3).

Dr. F. Blair Simmons, associate professor of surgery and head of the Division of Otolaryngology, will speak at 8 p.m. in Room M106 of the Medical School Building. His lecture is part of the medical school's PROGRESS IN MEDICINE series.

Dr. Simmons will discuss the symptoms and physical effects of spatial disorientation, usually called dizziness. He will also describe current methods of diagnosing the problem, particularly the technique of recording eye motion electrically.

Dr. Simmons has been a member of the Stanford faculty since 1961. He is a specialist in middle and inner ear surgery.

STANFORD -- A Tracy, Calif., man recently became the first patient to receive a mitral valve from someone else's heart, Stanford University surgeons have disclosed.

Rhoder E. Cundiff, 66, received a "fresh" mitral heart valve from a recently deceased person in an open-heart operation performed at the Palo Alto-Stanford Hospital Center.

Until this new technique was perfected (and even now) most patients received plastic heart valves to substitute for their own damaged valves.

Cundiff underwent open heart surgery last month and is now back home in Tracy. He is able to be up most of the day, watching television and rooting for the Giants.

"That's the best sounding valve I ever heard," Dr. Norman E. Shumway, professor and head of the division of cardiovascular surgery, told Cundiff after a recent examination.

Dr. Shumway and his associates have pioneered in transplanting both "fresh" mitral and aortic valves from persons dead not more than 12 hours. Seventeen aortic valve transplants have been reported by the Stanford University School of Medicine in recent weeks. But, Cundiff's was the first "fresh" mitral valve transplant.

The mitral valve guards the opening between the left auricle and ventricle, keeping blood in the ventricle from returning to the auricle.

Cundiff's valve had apparently been ruptured for some time. He had always worked hard physically, being labor foreman for a construction company. He knew something was wrong, but he did not know what.

"I was just short of breath. I did not know whether I could get across the yard or not," is how Cundiff described his awareness that all was not well.

The fresh heart valves used at Stanford are carefully selected. Donors cannot have suffered from infectious diseases or cancer. Cundiff and others receiving the fresh valves never know who their benefactors are.

Cundiff has improved so much that the doctors have taken him off the salt-free diet prescribed for many heart patients. In weight he is now to his normal 165 pounds (he was up to 189 before the operation).

Stanford Medical Center operates a heart valve "bank," but the supply is far too small for the need. It would welcome inquiries from persons who want to will their valves or who might make a donation from a family member who has just died. The bank's phone is 321-1200, extension 5771.

STANFORD -- The Stanford University School of Medicine today announced that Bertrand Goldberg Associates of Chicago will be the architectural consultants for its proposed hospital-ambulatory care center and new basic science building.

Goldberg, a leading architect who designed the famous Marina City in Chicago, will work with the medical faculty and other experts in the planning of the facilities. Ultimately his role will be to translate the emerging plan into a physical structure with maximum flexibility.

"Mr. Goldberg is an architect with an imaginative and scholarly approach to the problems of design, who is not wedded to the past," commented Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine. "Under his expert guidance we hope to apply new concepts of construction to the delivery of comprehensive health services that can be emulated throughout the nation."

The School of Medicine recently received a $500,000 planning grant from the Commonwealth Fund of New York to initiate studies toward a solution of the widespread national problem of escalating medical care costs. A chief factor in the problem is the relative inefficiency of architectural designs that limit patterns of utilizing staff, space, and equipment.

Stanford is taking advantage of its need for medical facilities to plan new ones that will continue to assume a superior standard of care and, at the same time, incorporate features to limit costs, Dr. Glaser said.

Goldberg, whose buildings are known for their "outer space image and inner space reality," has been responsible for structural innovations, based chiefly on recent advances in structural theory, mathematics and computer technology. By combining technological advances with studies of behavior patterns he has produced standards for shaping space more sophisticated than simple geometry.

-MORE-

In his Marina City project, Goldberg departed from the convention of rectilinear, post-and-beam design ("A nation that is attempting to reach the moon cannot go on building like that," he was quoted as saying), and used the vertical concrete shell as a structural core for the high-rise twin towers. The core received all horizontal and vertical loads from cantilevered floor slabs. With this approach, Goldberg achieved greater structural rigidity than conventional steel-framed towers at no greater cost. His choice of a circular building gave all apartments in Marina City sweeping views.

Goldberg's innovations have been incorporated in a score of educational, commercial, and residential buildings in several states. Among them, he designed the master plan for Affiliated Hospitals, Inc. in Boston, which includes a 750-bed general hospital that will serve as a major teaching and research facility for Harvard Medical School; a 176-bed clinical facility for Elgin State Hospital at Elgin, Illinois; and the State University of New York Health Sciences Campus.

He holds degrees from Harvard, the Illinois Institute of Technology, and Bauhaus. The latter is the architectural school of Walter Gropius, founded in Germany in 1919, which became known for its adaptation of science and technology to the field of art and architecture.

Stanford's proposed health facilities, which include a 400 to 500-bed hospital will embody two objectives. Facilities will be related to the specific stage of care required by the patient, from those needing minimal supervision to patients requiring round-the-clock intensive care. Comprehensive-care service, stressing ambulatory, or outpatient care, will be an integral part of this concept.

STANFORD -- You climb the steps and ring the bell of the white bungalow, and a little girl of perhaps two years rushes to the door. Batting her unbelievably long eyelashes, she says, "Hi. I am Laura Lyn."

When you ask to see mother, Laura Lyn beams forth an enchanting smile. With all that brightness radiating from the tiny face, the visitor doesn't see at first that the auburn-curled girl is perched on a sort of saddle raised over a small wheeled platform or "dolly." She has no arms and only one leg. You wonder what can there possibly be for this child to smile about.

Incredibly, there seems to be a great deal that Laura Lyn finds to smile about. Her story begins at the Birth Defects Study Center at Stanford University School of Medicine and its affiliated Stanford Children's Convalescent Hospital in Palo Alto, where a major portion of her rehabilitation treatment is carried out.

Laura Lyn Kratzer, two years old, goes to the Stanford Center three times a week to receive both physical and occupational therapy and for a check of the little chest harness she wears. Her two artificial arms are attached to this harness while another prosthetic device anchored around her waist provides her with a left leg, knee and foot. These prostheses function by means of muscle motion and pressure.

At the Center and the Convalescent Hospital Laura Lyn receives "integrated care." This means that a number of medical specialties are needed for her care and training--a pediatrician, an orthopedist, a prosthetist, an engineer, a physical and sometimes an occupational therapist, a psychiatrist or psychologist, a medical social worker, sometimes other specialists.

In 1963 a grant from the National Foundation helped establish the Birth Defects Center in the department of pediatrics of the Stanford Medical School. Its purpose is to train medical personnel in treatment, diagnosis, and recognition of the problems of patients with birth defects. A second and equally important objective of the Center is to do research, both in the clinic and the laboratory, to find ways of preventing birth defects.

Laura Lyn is surrounded by outstanding skills and ministered to with deep concern and affection. Everyone is wide-eyed over the child's progress--bringing a cookie to her mouth by her toes, combing her doll's hair or picture-drawing in the same way. Everyone watches breathlessly when, as a sort of third-act curtain when the consultation ends, she walks down the hospital corridor <u>alone</u> and without crutches(though the physical therapist is nearby ready to catch her if she totters).

Dr. Irwin A. Schafer, assistant professor of pediatrics at the School of Medicine and medical director of the Birth Defects Center, emphasizes Laura Lyn's high intelligence as factor in her rehabilitation.

-MORE-

"Laura Lyn is above average intelligence, an extremely bright, perceptive and sensitive child," he explains. "Before she was nine months of age she was fitted with her first prosthesis. She has just grown up to these devices, and she takes them in stride as she goes along. Learning how to use them is not simple, at any age.

"Of course, she will have many, many problems as she grows up. But because of her superior intelligence, and that of her fine parents, she should overcome many handicaps. A major factor in her remarkable progress is that, aside from the loving care of her father and mother, she has been under the constant study here of people who are intensely interested in and devoted to her."

In their home at Alviso, Calif., Gerald and Shirley Kratzer, her parents, are quite certain why Laura Lyn smiles.

"Laura Lyn very much wants to do things on her own," her mother says. "And though she is not yet two years old, it's difficult to do things for her. She lets me attach her little artificial arms and leg and take them off at night, but precious little else.

"Of course, there are some things for which Laura Lyn must depend on her father and mother." She doesn't talk yet in grown-up words, but she and her parents have a language of their own--call it intuition, if you like.

"So, much of the time we know what she wants and needs. Months ago, in her own secret way, she told us she wanted to look like her brother and her three sisters, who have all of their own legs and arms."

As Laura Lyn toot-toots on a flute, plays an auto-harp with a leather pluck held between her toes or turns on the stereo tape recorder, her father says that "Laura Lyn has the gift of appreciating music. We want to take advantage of that gift. If the occupational therapists at the Birth Defects Center give their approval, we would like in time to work up a little combo, made up of these children amputees, playing the xylophone, drums, flute, and so on."

When mealtime approaches, mother fastens on the little arms, and Laura Lyn practices with the fork and spoon (the child wears the prostheses now only at mealtimes but must soon begin wearing them all day).

Shirley Kratzer, who bequeathed her red hair to Laura Lyn, makes a point:

"Laura Lyn will be taught a vocation. You don't have security of any kind, including emotional security, without an occupation--even when you have all your arms and legs. Maybe in time she'll play in a band, or even sing, or perhaps write. Whatever it is, she will learn to do something professional."

The Kratzers were shattered when the child was born with the congenital disorder known as amelia, or complete absence of arms and legs, one or all of them. They experienced overwhelming feelings of guilt, of bewilderment over why fate had dealt them this severe blow, made all the more puzzling because their other four children were normal in every way. Moreover, so far as the parents could ascertain, there was no history of birth defects in either family.

Soon after their initial despair, Gerald and Shirley were invited to the first of several meetings with the staff of the Stanford Center. In addition, social workers called upon them at home. And slowly the parents began to understand, through sympathetic guidance, that (1) the tragedy was no fault of theirs, (2) that today rehabilitative medicine could achieve incredible feats in giving Laura mobility through prostheses, and (3) that in Laura Lyn they had someone most rare to cherish.

Would they face the challenge?

Seen in the light, Gerald and Shirley did not hesitate. They met the challenge with remarkable intelligence and accepted it almost with eagerness. In less than two years the result has been an extraordinary case of rehabilitation, both of the child and her parents.

#####

(Mailed June 26, 1967)

"Laura Lyn wanted to look like her brother and sisters who have all their own legs and arms." Here Dr. William M. Gilmore, chief of physical medicine and rehabilitation at Stanford Children's Convalescent Hospital, and clinical assistant professor of pediatrics at Stanford, fastens on the little arms with help from Mrs. Marguerite Dilley, chief outpatient physical therapist.

Science Writers: Story is based on papers to be presented at meetings of International Society of Transplantation in Paris, France, and the Society of Nuclear Medicine in Seattle, Washington.

FOR PM RELEASE THURSDAY, JUNE 22, 1967

STANFORD--Newer scientific advances have improved the success rate for kidney transplantation and have paved the way for transplants between unrelated persons, a Stanford University surgical research team reported today.

Early results of studies using the new methods were given simultaneously at scientific meetings in Paris, France, and in Seattle, Washington. The studies are supported by grants from the National Institutes of Health.

Each of the techniques reported focuses its attack on the problem of administering safely and at the optimum time the powerful drugs that control the rejection of foreign tissues by the body.

In Paris, Dr.Samuel L. Kountz, assistant professor of surgery, and Dr. Roy B. Cohn, professor of surgery at the Stanford University School of Medicine, told the meeting of the International Society of Transplantation about their technique which has successfully produced superior early kidney transplant function than drug treatments given orally or intravenously. Successful treatment of the first rejection is important for the long-term survival of the graft.

They reported that controlling the body's rejection factor through drugs injected directly into the kidney improves the success rate for kidney transplantation.

The technique consists of inserting a teflon catheter into the transplanted renal (kidney) artery for administration of immunosuppressive drugs locally. The drugs act on the site of the rejection usually detected by a decline in kidney blood flow. Successful treatment of early rejection is marked by an immediate return of blood flow toward normal.

-more-

The surgeons said the technique has advantages over oral drug treatment because it allows smaller doses to be given. Thus the tendency of these powerful drugs to suppress the body's immunity and render patients susceptible to infection is minimized.

"Of 20 animals treated by this technique, all have exhibited prolonged survival," the surgeons reported. "There were no rejection crises for 20 days after transplantation had taken place. All of the grafts showed excellent initial function."

The Stanford researchers reported similar results in 18 patients. Seventeen of the kidney transplants were between relatives, and one between unrelated persons. Only one death occurred after three months from infection in a mother-to-daughter transplant.

"All of these grafts showed excellent initial function with less toxicity compared to the nine transplants performed earlier using conventional techniques," the surgeons said.

In Seattle at the meeting of the Society of Nuclear Medicine, Dr. Shin Hwa Yeh and Dr. Joseph P. Kriss of Stanford's Division of Nuclear Medicine, reported their discovery of a fast-decaying radioactive compound (Technetium-99 (V)-citrate complex) which was found to be excreted rapidly by the kidney.

Physiological studies by Drs. Cohn and Kountz showed that the compound was excreted in animals at the same rate the kidney filters out waste products. The new drug is now used to measure kidney function and to monitor rejection of transplants more accurately than was previously possible.

These advances, coupled with improved methods of tissue-typing and cross-matching developed by Dr. Rose O. Payne at Stanford, have paved the way for transplants between unrelated persons, the surgeons said.

The first such operation was performed two weeks ago at the Palo Alto-Stanford Hospital Center. Mrs. Ralph Aceves, 37, of San Jose, California, and a mother of three children, received a healthy kidney from an unrelated donor.

Mrs. Aceves became ill a year ago of an inherited kidney disease. Both her brother and mother had died of the disease. About 15 relatives and friends volunteered to donate a kidney to save her life.

The donor selected to be the most compatible was James Weighill, a 25-year-old truck driver and father of four from Santa Barbara, California, who is married to Mrs. Aceves' niece.

Both recipient and donor are reported in good condition and have returned to their homes.

STANFORD -- Dr. Robert J. Glaser, vice-president for medical affairs and dean of the Stanford University School of Medicine, has been appointed to a 15-member national advisory committee on higher education to explore the relationship between colleges, universities and the Federal government.

The committee, appointed by John W. Gardner, secretary of Health, Education and Welfare, will report to him in July 1968.

"The growing partnership between the Federal government and the universities must be a relationship in which neither side exploits the other," Secretary Gardner said. "If we are to reap the benefits and avoid the dangers in the relationship, we shall have to understand it far better than we do now."

In the current fiscal year, the Federal investment in higher education is estimated at $4.6 billion. In 1962 the figure was $1.6 billion.

The committee will examine the present quality of relationships between higher education and the Department of Health, Education, and Welfare. The overall relationships of colleges and universities with the Federal government also will be reviewed. The committee will identify the problems which exist and make proposals for their solution.

The advisory committee membership represents both large and small colleges and universities, junior colleges, foundations and public and private institutions. Dr. Charles Hitch, vice-president of the university for administration at the University of California at Berkeley, also is a member.

Dr. Glaser was president of Affiliated Hospitals Center, Inc. and professor of social medicine at Harvard Medical School prior to coming to Stanford. Earlier he served as vice-president for medical affairs and dean of the School of Medicine at the University of Colorado.

"I SWEAR BY APOLLO THE PHYSICIAN..."

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the Stanford University School of Medicine, administers the Hippocratic oath to 48 graduating medical students at a convocation held at the Medical School earlier this week. This is the fourth class to complete Stanford's five-year medical curriculum. Beginning July 1, the new Stanford physicians will begin their internships at 43 hospitals in 20 states.

The average age of the graduating physicians is 27. Of the 48, seven are women. Twenty-three of the students are married and have a total of 21 children, 11 born during the last five years. Dr. James E. Hayes, the class president, quoted the figures to show that "our class members have not neglected certain social responsibilities during their five-year study of medicine at Stanford."

In addition to support from their parents, the graduating class members received $250,000 in financial aid from the Dean's office--about $5,200 per student during their five years of training. The 303 full-time faculty members gave approximately 4,700 hours of instruction to each student, excluding the time class members have spent in gaining additional degrees and in research.

FOR AM RELEASE SUNDAY, JUNE 18, 1967

ATLANTIC CITY -- Psoriasis, the stubborn skin disorder that brings anxiety, embarrassment or pain to four million Americans, remains a mystery in spite of determined efforts to conquer it.

But some progress was reported today.

After seven years of research, supported by the John A. Hartford Foundation, Inc., of New York, these facts clearly emerge:

· Psoriasis, which is marked by disfiguring, scaly spots and patches on many parts of the body, is initiated by a kind of local chemical alteration of the skin. With all the assembled knowledge of this reaction, scientists still cannot explain its basic nature. Studies suggest that the basic abnormality lies not in the fundamental nature of growing cells, but in a defect in the mechanism which controls growth of the epidermis, the outer layer of the skin.

· So far, skin from patients with psoriasis shows no chemical peculiarities when compared with normal skin. Researchers, however, think that some significant chemical change may still be at work, possibly related to hormones.

· Although no real "cure" for psoriasis can be claimed, in 38.5 per cent of the patients the disease may temporarily disappear either spontaneously or with known treatments.

The report was presented at the annual meeting of the Society for Investigative Dermatology by Dr. Eugene M. Farber, professor and head of the Department of Dermatology, and Dr. Alvin J. Cox, Jr., professor of pathology, at the Stanford University School of Medicine. Dr. Farber is also president of the Society.

-more-

The Stanford researchers described detailed studies of the natural history of psoriasis conducted among patients in the United States, with cooperation from practicing dermatologists. The studies show:

- Inheritance figures prominently in the incidence of the disease. Eighteen per cent of the patients who took part in the questionnaire reported a parent with psoriasis, 11 per cent reported a brother or sister, and 13 per cent identified more distant affected relatives.

- For patients with a genetic predisposition, skin injury may trigger psoriasis. Fourteen per cent of the patients said their psoriasis began at a site of an injury.

- Climate is a factor in the disease. Of the patients studied, 77 per cent reported their skin improved in hot weather and 88 per cent noted it was worse in cold weather. Seventy-eight per cent stated sunlight caused improvement, and 15 per cent reported their skin got worse on exposure to sunlight.

- There is a relationship between psoriasis and arthritis, but there are no clues as to the reason for this relationship.

- Emotional factors were thought to have aggravated the disease in 40 per cent of the patients.

Drs. Farber and Cox said that failure of any therapy to effect a permanent cure indicates that known drugs achieve their temporary success by inhibiting growth of the outer skin layer and not by removing the predisposition of the skin to psoriasis.

They emphasized that making accurate measurements of tissues and fluids from psoriasis patients is difficult with present laboratory methods. This raises questions about the validity of much research work today.

An example of the difficulties influencing psoriasis research are studies of skin lipids (fats). Many workers have attributed special significance to various changes that they identified in studies of skin lipids and have connected them to psoriasis, Drs. Farber and Cox said. Work conducted at Stanford by Dr. David I. Wilkinson has demonstrated beyond any doubt that errors relating to the collection of skin lipids have been responsible for erroneous conclusions.

Lack of adequate laboratory methods for cultivating some viruses has hampered efforts to rule out a viral cause for psoriasis. For this reason the researchers are reluctant to conclude that viruses do not play a role in this disease even though there is no specific reason to suspect a virous as a cause.

"As more sophisticated approaches become available from the massive screening programs currently used for the possible viral cause of leukemia, another and more extensive search should be made in psoriasis applying these new techniques," the researchers recommended.

STANFORD -- A noted Stanford cancer researcher Sunday urged medical school graduates to make their influence "strongly felt in reshaping the organizational framework of medicine, which for too many years has been dominated by men who have responded to the need for change by a policy of denial and negativism."

"Our county, state and national medical societies must become responsible and constructive instruments for dealing with the increasingly numerous and complex problems of medicine and public policy," said Dr. Henry S. Kaplan, professor and head of the department of radiology at the Stanford University School of Medicine. He spoke at a convocation for 48 graduating medical students, attended by 500 parents and faculty members at the medical school.

Dr. Kaplan said that all of the developments of the past few years reflect "an intense interest in health and desire for absolutely first class medical care on the part of the American people, who have shown themselves to be quite prepared to pay the bill for expanded medical research, hospital construction, tax-subsidized health insurance for the aged and indigent, and very recently for subsidization of medical education."

"It is imperative that we physicians remember that these things are happening because society wants them and feels a need for them, not because some politician or demagogue is selling grandiose schemes. There is a danger that, as physicians, we may tend to forget that we are servants of society," he said.

Dr. Kaplan suggested that the medical profession take the initiative in planning creatively and wisely for the health care needs of society. "Failure to do so will only mean that others less qualified will make such decisions for us," he said.

He said academic medicine is emerging as a "third force" in shaping medical practice patterns of the future.

"The medical school has long since cast off its former image as the 'ivory tower' and is now a bustling, extremely complex institution in which the education of undergraduate medical students is only a part," he said. "The rest of the program comprises patient care, medical education at the residency and fellowship levels, training programs for an increasing variety of paramedical personnel and a broad spectrum of basic and clinical research."

These changes in the nature and scope of the medical school have essentially created enormous stresses and strains for the faculty, students, and the administration, Dr. Kaplan said. As the role of the medical center expands, it becomes increasingly difficult to recruit adequate numbers of faculty members who can fulfill the classical expectation that they excel in teaching, patient care, and research.

-more-

"It is clear," he said, "that we must re-think the problem, perhaps along the lines of creating a new category of para-faculty medical staff to deal with our expanding patient care and postgraduate teaching responsibilities, thus freeing the faculty to do a more effective job of undergraduate teaching and research."

Dr. Kaplan predicted that the new regional programs for heart, cancer and stroke will thrust enormous additional responsibilities on the overburdened medical schools. However, they also present the schools with some new and challenging opportunities. Among them are:

· regional networks of affiliated hospitals utilizing computer data storage and retrieval systems, which, for the first time, will provide accurate information about the quality of medical care at the grassroots level and open new approaches to quality control.

· closed-circuit TV links between hospitals in such regional networks will permit the creation of a new kind of continuing post-graduate medical education program on a nationwide level, and will enable the medical schools to keep the level of education high during the physicians' practice.

· regional affiliations will greatly expedite and accentuate the dissemination of new discoveries to the smaller community hospitals throughout the nation.

He said medical research has had an enormous impact on medical education and medical practice. The medical curriculum has placed much emphasis on the basic sciences and on education rather than "training," so that every doctor emerging from medical school today "must be able to assimilate and evaluate for himself the tremendous body of new information and new discovery that will come forth in the next 25 years."

Some of the things to come, Dr. Kaplan said, are new vaccines against viruses, elimination of major insect and parasitic infections, and proof that the cause of certain human cancers, probably leukemias and related lymphomas, is due to viruses and development of specific vaccines for prevention.

FOR RELEASE MONDAY, JUNE 12

Editors: Names of students receiving M.D. degrees in your area will be included in a story mailed from Stanford University June 16. Home addresses of award winners are listed on page 2.

STANFORD -- Stanford University School of Medicine presented awards to seven graduating students at the annual senior class convocation Sunday (June 11).

Degrees will be awarded June 18 to 41 men and seven women, members of the fourth class to complete Stanford's five-year medical curriculum. The five-year program was inaugurated when the medical school moved from San Francisco to the Stanford campus in 1959.

At the convocation, John D. Minna received the Dr. and Mrs. Joseph Fife Surgery Award of $200 and the Stanford Medical Alumni Scholarship Award of $400. The Fife Award is given to an outstanding student in surgery, and the Alumni Award is in recognition of high scholastic achievement and leadership.

Richard G. Offutt received the Robert H. Alway Book Award, the L.A. and Marian S. Hopkins Award in Dermatology and the Lowell A. Rantz Memorial Award.

The Book Award, named in honor of Dr. Alway, dean of the medical school from 1958 to 1964, is given to a student who has "availed himself especially well of the Stanford five-year plan." The Hopkins Award, $100, is given to an outstanding senior medical student in dermatology and the Rantz Memorial Award, $125, to the student who has distinguished himself in the field of infectious diseases.

The Harold K. Faber Pediatric Award, $200 each, was presented to Helen Cheng-shan Li and Edgar K. Marcuse. This award honors potential contributors to child health in recognition of accomplishments in pediatrics.

Peter W. Wright received the $500 Borden Undergraduate Research Award in Medicine, given by The Borden Company Foundation, Inc., to the senior student who has completed the "most meritorious" research during his medical training.

-more-

David M. Treiman was presented the $250 National Foundation Merit Award for outstanding research in the area of birth defects, and Thomas D. Lindell received the $200 Upjohn Achievement Award for outstanding clinical performance.

Dr. Bernard W. Nelson, assistant dean for student affairs, presented the awards, and Dr. Harold K. Faber, emeritus professor of pediatrics, announced the recipient of the award named in his honor.

Class president James E. Hays presented the annual Arthur L. Bloomfield Award for excellence in the teaching of clinical medicine to Dr. Leon Cohen, assistant professor of medicine (neurology).

Dr. Henry S. Kaplan, professor and executive head of the department of radiology, delivered the faculty address, and Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, administered the Hippocratic Oath.

A special feature of the program was a performance by the Shawm Band, a group of five musicians who play medieval woodwind instruments.

Award winners and their parents' names and addresses are listed below:

CALIF., DOWNEY - Richard G. Offutt, Mr. and Mrs. W.V. Offutt, 8523 E. 11th St.

LOS ANGELES - David M. Treiman, Mr. and Mrs. A.A. Treiman, 1519 Easterly Terrace

SAN DIEGO - John D. Minna, Dr. and Mrs. John B. Minna, 1859 Fort Stockton

CONN., WILTON - Peter W. Wright, Mr. and Mrs. Robert Wright, 489 Danbury Rd.

HONG KONG, HAPPY VALLEY - Helen Cheng-shan Li, Mr. and Mrs. Tsun-kai Li, 49 Village Rd.

NEW YORK, N.Y. - Edgar K. Marcuse, Mr. and Mrs. J.E. Marcuse, 1125 Park Ave.

OREGON, ROSEBURG - Thomas D. Lindell, Mr. and Mrs. E. Lindell, 358 S.E. Claire St.

STANFORD -- The study of tropical diseases is not as far removed from practical medical education as Californians might think.

Dr. Quentin M. Geiman, professor of preventive medicine at Stanford University School of Medicine, says he has seen more tropical or parasitic infections in California in one year than he saw in 10 years in New England.

During the past year, Dr. Geiman reports, he has identified 83 positive parasitic infections, including eight cases of malaria and several cases of amoebic dysentery and worm infestations.

Dr. Geiman believes the increasing incidence of parasitic infections can be traced to military personnel returning from Vietnam, peace corps returnees, representatives of the diplomatic service, widely travelled Californians and the large number of foreign born individuals who settle here.

He also calls California "a jumping off place" to Asia, Mexico, Central and South America. The state, he says, is in an excellent geographical position to concern itself with tropical health.

"Tropical diseases are not simply something you read about in books," Dr. Geiman emphasizes. "We have so many of our own medical problems in this country, it is easy to ignore problems of international health. But they are not as far removed as we might think."

Dr. Geiman was on the faculty of the Harvard School of Public Health for 20 years before coming to Stanford in 1955. In addition to his teaching responsibilities at the medical school, he heads the Palo Alto-Stanford Hospital Center diagnostic laboratory for the detection of animal parasites.

He also directs the medical school's Tropical Health Training Program, which awards travelling fellowships to students interested in obtaining clinical experience in a developing country. Since the program was organized eight years ago, 39 students have used vacation and free time to study in Mexico, Central and South America, Jamaica, Africa and the island of Martinique in the West Indies.

The purpose of the program, Dr. Geiman explains, is to provide instruction in the diagnosis, treatment, control and prevention of human diseases in subtropical and tropical climates.

The program is designed to encourage and maintain the interest of students in public health and to give them more experience with acute illness. "Problems of medical care in a developing country are basically similar to our own," Dr. Geiman adds, "but they are more clear-cut and subject to decisive control. Experience in solving them is good preparation for the study of public health in this country." -more-

To qualify for a travelling fellowship, the student must complete an elective course in tropical health and have a working knowledge of the language of the country to which he is assigned. Organizational and travel costs are paid under a training grant from the National Institutes of Health.

Dr. Geiman personally visits each of the countries to set up the program for the students. He works with government officials, medical school faculties and ministers of health.

This year a third year medical student is spending a travelling fellowship in Martinique and a fourth year student is in Ethiopia. Two others have recently returned from Jamaica, Costa Rica and Mexico.

The program in Martinique is one of the most unusual. It was organized by fifth year student Richard Offutt, who spent the summer of 1964 on a travelling fellowship to the island. During his stay, Offutt set up a work-study plan with the director of the Leprosarium in the Martinique Hospital.

Although the clinical experience in Martinique focuses on the treatment of leprosy, the visiting student also has the opportunity to study the general diseases of the people. Of the 1,000 lepers on the island, Offutt explains, only about 200 are hospitalized at any one time, and these have acute complications usually not related to leprosy.

Offutt also took a leave of absence to study medical problems in Africa. He spent four months in the Union of South Africa and four months in Uganda, East Africa.

He stresses that the majority of diseases in Africa and Martinique are the same as those found in the United States. The only difference, he says, is that diseases in tropical countries are usually of longer duration and more severe.

"An African with diabetes will come to the hospital in a coma, while diabetes in an American is usually detected in a mild form at an early age."

Thus, Offutt concludes, the learning experience in a tropical country is directly transferable to this country--"with the added challenge of studying another culture and way of life."

Because of the growing student support of the Tropical Health Training Program, Dr. Geiman and other interested faculty members are now exploring ways to expand the medical school's curriculum to cover the broader field of international health.

"Today's students have a great desire to travel and to improve the world," Dr. Geiman says, and he strongly believes "this type of student interest deserves to be nurtured."

STANFORD -- The Stanford University School of Medicine Monday dedicated the Valerie and Harry Corvin Clinic for Diseases of the Skin and announced in conjunction a gift of $120,000 to support the work of the Department of Dermatology.

The gift is from Mr. and Mrs. Harry Corvin of San Francisco. Corvin was born in Boston and came to San Francisco in 1908. He is an attorney who has specialized in corporation law and estate planning.

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, praised Mr. and Mrs. Corvin for their "public-spirited support. Their gift is a boon to the School of Medicine, to patients who seek care here and to those who teach and do research. It is a gratifying manifestation of the encouraging support Stanford receives from enlightened citizens of the San Francisco Bay area, and it will be very valuable in the development, research and teaching of dermatology."

The Corvin Clinic contains examining rooms, a laboratory and X-ray room, and facilities for minor surgery. It is a part of the Stanford University Clinics.

CAPTION (Photographs available per attached photocopies.)

This whimsical copper and bronze sculpture of a scene in the operating room won top honors in the annual employee art show at Palo Alto-Stanford Hospital Center. The sculpture, entitled "The Operation," depicts two surgeons working on a body-shaped sheet on the operating table, while the patient sits behind the ether shield playing cards with the anesthesiologist. In front of the table, a nurse steps on the doctor's gown as she tries to help him into it, to the back another nurse tries to sort out a tangle of sutures, and at the far right, two interns fight over who gets to hold the retractor (an absurdity because no one wants to hold the retractor). The artist is Dr. Raymond Stofer, research associate in surgery at Stanford University School of Medicine. He spent about 11 months working on the sculpture. Each piece was individually shaped in copper, then assembled and brazed with a bronze coating to harden the surface.

EDITORS: Story is mailed simultaneously with the release from Commonwealth Fund of New York. Release date set by Commonwealth Fund.

FOR A.M. RELEASE THURSDAY, JUNE 1, 1967

STANFORD -- The Stanford University School of Medicine has received a $500,000 grant from the Commonwealth Fund of New York to initiate planning for a new hospital and ambulatory care center and to advance fundamental reforms in the patterns of hospital services and education in the health professions.

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, said the Commonwealth Fund's generous grant will assist Stanford to undertake "a creative enterprise that will encompass physically a new concept in hospital construction and the delivery of comprehensive health services."

He said the planning studies to be undertaken by the School of Medicine are directed toward a solution of the widespread national problem of the escalating scale of hospital costs, fast becoming a foremost issue in health financing.

A chief factor in the problem is the relative inefficiency, in terms of the health-care return on the dollars expended, of prevailing hospital designs and patterns of utilizing staff, space, and equipment. Stanford is taking advantage of its need for a new hospital to plan a facility that will assure a superior standard of care and, at the same time, incorporate features to limit costs.

The planning project will extend for a period of two years. The Commonwealth Fund's grant will be used chiefly toward the costs of a small planning staff and consultants in such fields as architectural design, management systems, computer technology, and automation processes and equipment. These experts will collaborate with the medical faculty and scholars in relevant nonmedical departments and schools of the University--for example, economics, sociology, and engineering--in the design of both the physical structure and operational system of the new hospital and ambulatory care center.

The proposed health facilities are part of the Medical School's master plan now under development, which also envisions construction of a new basic science building for the departments of Anatomy, Physiology, Pathology, and Medical Microbiology.

Dr. Glaser said the planning studies will constitute a fundamental examination of the hospital as a service system, with emphasis on the application of modern managerial techniques and engineering technology in achieving optimum use of available resources. The studies will seek to determine how staff should be trained and deployed to serve the hospital patient-care responsibilities most advantageously, what aspects can be automated, and what design concepts would be most suitable.

-more-

"The operating patterns of the nation's large hospitals, with multi-million-dollar budgets, have not been subjected to the kind of scrutiny that is employed in industry," Dr. Glaser said. "For example, most hospitals have very large nonprofessional staffs, with high turnover rates. As a result extraordinarily high costs are incurred. No multi-million-dollar enterprise in the competitive world would prosper under such circumstances."

Dr. Glaser said the new hospital design will embody two objectives. First, facilities will be related to the specific stage of care required by the patient, from those needing minimal supervision to patients requiring round-the-clock intensive care. In contrast, most hospital patients now tend to be treated in facilities that assume identical seriousness of illness and involve the same cost to the patient and the hospital. Second, a comprehensive-care service, stressing ambulatory, or outpatient care, will be an integral part of this multi-stage hospital concept.

"Nationwide, there is a serious lack of innovative planning for hospitals," Dr. Glaser commented. "We need to show the way for vitalizing obsolete hospitals and to articulate a program for research and demonstration projects that would help find new and improved ways of organizing and delivering health services. This would raise the quality of care, increase the efficiency of operation and render hospitals more suitable as centers for research and training."

Dr. Glaser said that Stanford's new plans will make it necessary for the City and the University, joint owners of the present 437-bed Palo Alto-Stanford Hospital, to alter their present relationships. "The Medical School's diverse research, education, and patient care needs have made all the more apparent the necessity of an independent University-controlled hospital."

Stanford has about 200 beds in the present hospital. The School of Medicine has stated it needs 400 to 500 beds to carry out its mission.

STANFORD -- Dr. Hayes A. Newby, professor and director of the division of speech pathology and audiology at Stanford University School of Medicine, has been appointed a professor in the department of communication arts and sciences at Queens College of the City, University of New York (CUNY).

At Queens College, Dr. Newby will teach audiology and will head the area of communicative disorders within the department. He will also be a member of the committee that is responsible for the doctoral program offered by CUNY.

Dr. Newby has been associated with the University's department of speech and drama since 1947. He joined the medical school faculty in 1957 and was appointed director of the division of speech pathology and audiology in 1963.

Dr. Earl D. Schubert will succeed Dr. Newby as acting director of the division.

Dr. Newby received his B.A. at Ohio Wesleyan University in 1935 and his M.A. (1939) and Ph.D. (1947) from the University of Iowa.

He is a past president of the American Speech and Hearing Association and the American Boards of Examiners in Speech Pathology and Audiology, a branch of ASHA. For the past seven years, Dr. Newby has served as moderator of the weekly television show "Doctors News Conference" which appears on Channel 2, Oakland.

Dr. and Mrs. Newby will move to the East Coast next month.

#####

STANFORD -- Dr. C. J. Karzmark of the Stanford University School of Medicine has been awarded a $22,000 grant for research in radiologic physics and radiotherapy at M.D. Anderson Hospital and Tumor Institute in Houston, Texas.

The grant, one of nine to California scientists for cancer research, was announced today by the California Division of the American Cancer Society.

Dr. Karzmark, an associate professor in the Department of Radiology, will take a leave of absence beginning in September. In 1962 he took a leave of absence to be in residence at the University of London on a U.S. Public Health Service fellowship program. He has been associated with the School of Medicine since 1955.

An authority in radiologic physics, Dr. Karzmark did undergraduate work at Yale, Harvard, Massachusetts Institute of Technology and the University of North Dakota, where he received his B.S. degree, with honors, in 1947. He received his M.S. in 1948 and a Ph.D., summa cum laude, in 1952 from Indiana University.

Over 1.5 million dollars in research grants have been awarded by state and national organizations of the American Cancer Society to California Institutions since September 1966.

STANFORD -- The Stanford University School of Medicine has received a $281,000 matching grant from the National Institutes of Health for construction of an Animal Research Center, proposed to be one of the most advanced of its kind in the nation.

The announcement was made today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine.

The center will be located on Stanford land in the foothills just southwest of the main campus. The proposed buildings will contain approximately 14,000 square feet of space with an additional 4,000 square feet of outdoor pens and kennels.

According to Dr. Orland Soave, director of the Animal Care Facilities and clinical associate professor of medical microbiology, the Center will provide better animal care than is possible under present conditions and will provide room for expansion of research and teaching programs for the future.

Dr. Soave currently heads a staff of 35 who provide care for the over 65,000 animals housed each year by the medical school and used by nearly half of the faculty and staff for research.

"An important factor contributing to the over-taxing of present facilities has been the almost 300 per cent increase in medical school faculty--from 115 in 1957 to 310 today--and the concomitant growth of research," Dr. Soave points out.

Design features of the new Center will include outdoor exercise areas as well as excellent indoor housing, radiant heating where necessary, automatic flushing of pens, and automatic watering devices.

The central facility, a single story building of reinforced concrete, will provide laboratories for the study of animal diseases, operating rooms, research laboratories and support facilities.

"The laboratory animal is sensitive to environment changes, and it is vital to provide the highest level of care so that the animals will be maintained in a healthy state, as near to normal as possible," says Dr. Soave.

"The use of animals for biomedical research is essential for the advancement of knowledge related to our ability to conquer disease and elevate the standards of health throughout the world," he says. "However, we must use them in a humane way and care for them in a manner consistent with today's knowledge of animal husbandry and veterinary medicine.

"In addition," Dr. Soave stresses, "is the fact that animal research often benefits animals as much as it does man. The vast majority of our knowledge concerning the treatment of animal diseases has resulted from their use in the study of human ailments. Such knowledge is then adapted to animal care." -more-

The new Animal Research Center will:

--permit optimum care for the animals used in biomedical investigation.

--serve as a holding area for animals that must be quarantined and conditioned prior to research use.

--house large domestic animals, i.e., cows, horses, sheep, pigs, that require an outdoor environment, and those long-term research animals that require only infrequent testing or observation.

--permit the study of animal diseases, both natural and induced, that will be of value to physicians and veterinarians.

--provide professional consultation for the diagnosis and treatment of diseases in animals, research on laboratory animal problems, and training in animal care and medicine. (This will include an expansion of Stanford's postdoctoral training of veterinarians in the field of laboratory animal medicine, under the direction of Dr. Soave.)

--provide for the maintenance of highly inbred strains of animals, such as mice, in an isolated environment in order to minimize contamination.

--provide housing for wild or exotic species from anywhere in the world that exhibit clinical diseases or abnormalities worthy of investigation.

One of the major research programs requiring the additional facilities which the new Center will provide is the newly initiated program in comparative medicine.

This effort relates to the study of natural-occurring diseases of animals that are either similar, identical, or closely related to human ills. In such instances, the disease process can be observed from birth to death and every phase of its development studied. Animals so afflicted can be inbred to determine the effect of selective breeding on disease and further, since the life span of animals is usually much shorter than that of man, the natural history of diseases can be better defined.

"In spite of the tremendous advances in medicine in the past 50 years, there are still many unknowns--cures for cancer, diseases of the heart and circulation, and the problems of aging and mental retardation. Undoubtedly, animal research will play an important role in research directed toward the solution of these problems in the future," says Dr. Soave.

Science Writers: Story release date is set to coincide with presentation of scientific paper by Dr. Karasek at International Congress of Dermatology in Munich, West Germany. In Munich Dr. Karasek can be reached at Pension Roschlein Luisenstrasse 55.

FOR AM RELEASE MONDAY, JULY 31, 1967

MUNICH -- A Stanford University biochemist today reported that the outer layers of skin can be successfully reconstructed from cells grown in a test tube.

Dr. Marvin A. Karasek told the 13th International Congress of Dermatology here that cells taken from a rabbit and cultured for 14 days in a test tube grew normally when transplanted back to the host animal and that the grafted cells formed a new epidermis, the outer layer of skin.

Dr. Karasek said the transplanted cells and newly-formed epidermis survived for as long as five weeks after grafting, and the cells maintained their potential for growth and differentiation during this period.

The finding runs counter to the common belief that cultured adult skin cells have no ability to form a specific tissue. "When placed in an appropriate physiologic environment, the cultured adult epithelial cell again resumes its normal growth and differentiation," Dr. Karasek said. Although cells have been transplanted before by others, this is the first time cells have been successfully grown after culture in a synthetic medium.

Dr. Karasek is an assistant professor of biochemistry in the department of dermatology of the Stanford University School of Medicine. One of his chief interests is learning more about the complicated biochemical reactions that lead to uncontrolled growth of cells in patients with skin diseases. The work is supported by grants from the John A. Hartford Foundation, Inc. of New York, and the National Institutes of Health.

-more-

He said the use of cultured skin cells for studies of wound healing has been an attractive possibility since the development of cell culture techniques, but that the behavior of such cells after transplantation has never been established. One of the difficulties has been the interference with grafts by the normal wound healing reactions. For his studies, Dr. Karasek developed a silicone rubber chamber that blocks normal wound healing and permits only transplanted cell growth.

Dr. Karasek reported these observations from the rabbit transplant experiments:

· One week after transplantation of the cells to the prepared graft site, the epithelial cells multiplied to form a cell layer over the entire wound site that was three cells in thickness.

· Two weeks later the cells had formed an epidermis that was 5 to 10 cells in thickness. Keratinization, the formation of the corneous or horny outer normal skin layer, also appeared during this period.

· After three weeks, the newly-formed epidermis became extra-thick because of an abnormal increase in the number of cells.

· Five weeks later the new epidermis began to show deterioration signs and to flake off.

"We are not sure why this skin is not permanent," Dr. Karasek reported. "It is possibly due to some unexplained immunologic mechanism or because we have not yet achieved the proper physiologic environment for these cultured cells to survive for a longer period."

He added, however, that from a biological viewpoint, this development represents a "rare opportunity to test the changes that occur when a cell is grown in a foreign environment. The explanation of the changes that take place is one of the most challenging and important areas in cell biology."

FOR FURTHER INFORMATION CONTACT: Jane Duff (321-5310)

STANFORD -- Dr. George R. Murray Jr., an expert in system analysis, has been appointed director of the Stanford Medical Facilities Planning Group.

The announcement was made today by Dr. Robert J. Glaser, vice-president of medical affairs and dean of the School of Medicine.

Dr. Murray, 36, and a staff of nine specialists will collaborate with the medical faculty and experts in relevant nonmedical departments and schools of the University in the design of both the physician structure and operational system of the proposed new hospital and ambulatory care center.

Staff members, from such fields as system analysis, economics, hospital management and computer technology, include Chief System Analyst Dr. Richard D. Smallwood, assistant professor of engineering-economic systems at Stanford, and his staff, Fred L. Offensend, Daniel D. Silva and Edward J. Sondik.

James Stanford, currently assistant to the financial vice-president of General Mills, Inc., will join the planning group next month. Other staff members will be selected by fall.

Dr. Murray and his staff will work with Bertrand Goldberg Associates of Chicago, recently named as architectural consultants for the proposed expansion.

"Medical science to date has focused on specific techniques of diagnosis and treatment," says Dr. Murray. "Relatively little thought has been devoted to the total system by which health care is administered.

"Stanford is unique in having on one campus both a major medical school and a department of engineering-economic systems devoted to the design of complex technical-economic systems."

-more-

"Our study will concentrate specifically on patient care and the teaching function of a medical school hospital. I regard this as an example of interaction between medicine, technology and engineering that can lead us to more effective and less costly health care systems," Dr. Murray comments.

The School of Medicine recently received a $500,000 planning grant from the Commonwealth Fund of New York to initiate studies toward a solution of the widespread national problem of escalating medical care costs.

During the study, Dr. Murray will take a leave of absence from the department of engineering-economic systems at Stanford where he has been an associate professor since 1965.

Before joining the University faculty, Dr. Murray had six years of industrial systems analysis experience as a member of the operations research staff of Arthur D. Little, Inc., and as a research associate at the operations research center at Massachusetts Institute of Technology. He has also served as a consultant for General Electric Co. and Stanford Research Institute.

Dr. Murray received his B.A. degree from Harvard in 1952 and a Ph.D. from M.I.T. in 1956.

Stanford's proposed health facilities, which will include a 400 to 500-bed hospital, will embody two objectives. Facilities will be related to the specific stages of care required by the patient, from those needing minimal supervision to patients requiring intensive care. Comprehensive-care service, stressing ambulatory, or outpatient care, will be an integral part of this concept.

Editors: Story released simultaneously by the National Foundation.

The Stanford University School of Medicine has received a grant of $69,403 from the National Foundation-March of Dimes to continue its search into the causes, treatment and prevention of birth defects.

The grant was announced jointly today by Robert J. Glaser, vice-president for medical affairs and dean of the medical school, and Basil O'Connor, president of the Foundation.

Stanford operates a birth defects study center as a unit of its department of pediatrics. The center, established by the National Foundation in 1963, is directed by Dr. Norman Kretchmer, professor and executive head of the department.

Among investigations under way at the center is a study of the role played by Vitamin C in Hurler's disease (gargoylism). An estimated one in 10,000 infants is born with Hurler's disease. They look normal at birth. But during the first two years of life, the head enlarges, the features thicken and growth is stunted to the point that the children resemble medieval gargoyles. Their brains are often affected and sometimes they have difficulty in learning to speak or walk. The victims usually die at an early age from enlargement of the heart, liver or spleen.

Though the body chemicals causing this inherited disease have been identified, the Stanford researchers feel that another look at the way body cells produce these chemicals may offer better understanding of the disease. They are also looking into the possibility that Vitamin C, commonly found in fruit juices, may be implicated.

Taking a tiny piece of skin from Hurler disease victims and a similar culture from normal subjects, the Palo Alto team added Vitamin C to both. There was no significant change in the normal cultures. With Hurler's, however, Vitamin C increased a chemical reaction, which occurs to excess in these patients, and is thought to cause the thickening of various body parts.

STANFORD -- A $21,000 grant has been awarded to the Stanford University School of Medicine to increase the number of physicians training in anesthesiology, and to upgrade the quality of the training program.

The new program, supported by the National Institutes of Health, is part of a national effort to improve patient care by expanding anesthesiology training.

Dr. Ellis N. Cohen, professor of anesthesia, will direct the program.

"The increased complexity of today's medical care has opened many new areas in which the anesthetist is now concerned, and expanded training programs are required to meet these additional needs," Dr. Cohen points out.

"The scholarly environment in a teaching hospital such as ours is an essential element to the training of highly qualified clinical anesthesiologists," he says. "Our clinical and teaching faculty can provide a high level of training in both the basic and the clinical sciences."

Two candidates will be chosen from present applicants or from residents currently in the anesthesiology residency program. Initial training will begin this fall. Plans call for a third trainee to be selected for next year, and two additional trainees in 1969-70.

The curriculum will incorporate the present two-year program in anesthesiology and provides an additional year of special training. One of the two trainees will direct his third year towards the anesthetic management of the patient for cardiac surgery, and the second trainee will spend his third year in acute medical care.

The Stanford grant is part of a million dollars awarded to 30 teaching hospitals in 21 states and in Puerto Rico for anesthesiology training programs.

Editors: Story released simultaneously by the National Foundation.

Children born with the defect known as myelodysplasia (open spine) usually cannot control their bladders naturally, but Stanford University scientists hope to develop an electrical device to do the job artificially.

The research project will be conducted by a Stanford University School of Medicine team headed by Dr. Duncan E. Govan, associate professor of surgery, with the help of a $69,492 grant from the National Foundation-March of Dimes.

The grant award was announced today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school, and Basil O'Connor, president of the National Foundation. With this grant March of Dimes support for medical research and professional education at Stanford now enters its 30th year and totals more than $2,000,000.

Dr. Govan hopes to develop an electrical device through which a child can control his bladder much as the artificial pacemaker regulates the speed of the human heart.

When a child is born with an open spine, Dr. Govan explained, the nerve connections, through which the brain controls the bladder, are either weak or completely absent. The device that Dr. Govan hopes to perfect would eliminate bladder incontinence and its emotional consequences. Bladder self control would also help to reduce the constant threat of bladder infection and kidney damage so common among children with myelodysplasia (open spine).

The project is part of a broad clinical and experimental research conducted by the Division of Urology of the Stanford University School of Medicine. It is designed to study all aspects of bladder dysfunction due to bladder nerve damage.

The work of Dr. Govan and his associates promises to be a vital part of the nationwide effort of the March of Dimes to help victims of "open spine" lead a normal life.

STANFORD -- A special fund to financially assist medical students has been established in the name of Paul Edward McNamara, according to Dr. LeRoy A. Pesch, associate dean of Stanford University School of Medicine.

"Generous gifts continue to be received," he notes.

The memorial fund, founded in cooperation with Mr. McNamara's parents after the 23-year-old medical student's death, will provide for student needs in the form of loans or grants, explains Dr. Pesch. It will be administered, beginning in the fall, by the School of Medicine.

Preference for money from the fund will be given to needy members of the Class of 1970 of which Mr. McNamara was a member.

Mr. McNamara, son of Dr. and Mrs. P.E. McNamara, 521 First St., drowned while scuba diving in rough seas near Carmel, Calif. last March.

STANFORD -- A research team at Stanford University School of Medicine has developed an electronic monitoring system to prevent mortality and brain damage in premature infants suffering from respiratory disorder.

The monitoring system is used to detect sudden cessation of breathing, a condition known as apnea. Apnea occurs in approximately 30 per cent of all infants weighing less than 5½ pounds.

Dr. William J. Daily, assistant professor of pediatrics and principal investigator, Dr. H. Belton Meyer, postdoctoral fellow in pediatrics, and Dr. Marshall Klaus, assistant professor of pediatrics, worked with engineers at Beckman Medical Instruments and Industrial Medical Instruments to develop the apnea monitor. It was tested in the Clinical Research Center for Premature Infants at Palo Alto-Stanford Hospital Center.

According to Dr. Daily, the purpose of the monitoring system is to detect apnea early enough to prevent death and possible brain damage in the developing premature. Once detected, treatment is usually an easy process. The nurse may simply "tickle" the child or in some other gentle way "remind him that he is here."

"The sudden and silent onset of apnea requires that the infants be watched constantly," Dr. Daily said. Even though the research center usually has one nurse for every two premature infants, the physicians felt surveillance could be improved.

The new device incorporates a warning alarm system based on fluctuations in electric current between electrodes attached to the infant's chest. When the infant stops breathing, the variations in electric current cease. An alarm is activated 20 seconds later to alert the nursing staff.

Thirty seconds after breathing stops, the nurse gently rubs the infant's skin. If breathing is not quickly re-established, she administers bag and mask oxygen resuscitation.

The researchers monitored 22 normal prematures for periods varying from five to 16 days. A total of 540 apneic episodes of 20 seconds or longer was observed in 13 of the 22 infants.

In 35 per cent of the 540 episodes breathing began spontaneously prior to skin stimulation. In an additional 55 per cent, breathing was re-established in association with stimulation and in 10 per cent, bag and mask resuscitation was necessary.

"The infants requiring resuscitation were, in essence, in a state of shock, unconscious, unresponsive, limp, hypoxic and had a bluish skin tone," Dr. Daily said. "We presume brain damage may occur under these circumstances, but this will require further study."

-more-

Hypoxia (insufficient blood oxygen) following prolonged apnea has been suggested as one cause of brain damage in small premature infants, he explained. "If apneic hypoxia is responsible for neurologic abnormality, it should be preventable using an appropriate warning system and early resuscitative measures."

Only one of the 13 infants with apnea died, Dr. Daily reported, and the death was not attributable to apnea. Ten years ago approximately 50 to 60 per cent of infants with prolonged apnea died.

Although the researchers primarily focused on detection of the disorder, Dr. Daily foresees varied applications of their findings. They discovered, for example, that a warmer environment increases the number of apneic episodes.

The abdominal skin temperature of the premature is usually kept between 35.8 and 37.2°C. Within this temperature zone, metabolic processes and oxygen requirements are thought to be at a minimum. When the abdominal skin temperature of five infants with apnea was increased from 36 to 36.8°C, the number of apneic episodes more than doubled.

The Stanford pediatricians believe this finding will increase interest in temperature as a significant determinant in breathing control mechanisms. It has further implications, they said, for the specifications of incubators.

They also found that certain changes in the heart rate and breathing pattern of infants with prolonged apnea resemble the adaptations of diving mammals. Current research on diving mammals, such as seals, may give scientists a better understanding of the effects of apnea.

Even more important, such new electronic devices may lead to the development of a one-unit incubator and monitoring system for the continuous surveillance of all premature infants.

Attention science writers (transmitted on Business Wire 8/30/67):

Approximately 500 geneticists from the United States and abroad will attend the annual meeting of the Genetics Society of America at Stanford University Thursday through Saturday (Aug. 31 - Sept. 2).

Among participants will be four eminent geneticists from the Soviet Union, headed by Professor B. L. Astaurov, president of the Genetics and Selection Society of the U.S.S.R.

Three concurrent sessions on "Population and Quantitative Genetics," Molecular Genetics and Gene Action," and "Cytogenetics," will be held Thursday and Friday from 9 a.m. to 12 noon.

Dr. Joshua Lederberg, professor and executive head of the Department of Genetics at the Stanford University School of Medicine, will address the meeting Thursday at 8 p.m. at Dinkelspiel Auditorium. He will speak on "Experimental Genetics and Human Evolution." Chairman for the evening session will be Dr. E. B. Lewis of the California Institute of Technology and president of the Genetics Society.

Dr. David Hogness, professor of biochemistry at the Stanford University School of Medicine, will give the Friday evening lecture at 8 p.m. in Dinkelspiel Auditorium. He will speak on "The Arrangement and Regulation of Genes in Viral Chromosomes."

Other topics to be covered at the sessions include radiation genetics, genetics and metabolism, and recombination.

Details and programs for the sessions can be obtained from Mr. Fred Kettelkamp at the Society's headquarters, Wilbur Hall. Telephone (Area Code 415) 323-2300, Ext. 4144.

STANFORD -- Dr. David Korn, a pathologist and senior investigator in the National Institutes of Health at Bethesda, Md., has been appointed professor and executive head of the department of pathology of the Stanford University School of Medicine.

His appointment, culminating a two-year nationwide search by a faculty committee, was announced today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine. Dr. Korn's appointment will be effective June 1, 1968.

Dr. Korn, whose interests lie beyond the field of pathology into fundamental areas of biochemistry and mechanisms of life processes, is a senior staff member at the Laboratory of Biochemical Pharmacology of the National Institute of Arthritis and Metabolic Diseases, and an assistant pathologist at the National Institutes of Health. His published research includes 22 papers in the field of pathology and biochemistry, the latter dealing with studies of the basic mechanisms controlling the functions and development of bacterial viruses.

Dr. Glaser praised Dr. Korn as "an outstanding pathologist who understands what is happening in modern biomedical science and who promises to bring a new kind of leadership to Stanford and to academic pathology in general."

Among Dr. Korn's first responsibilities will be to plan for an expanded quarters for the department of pathology in Stanford's proposed basic science building that will be compatible with the demands of modern medicine and new approaches to the study of disease.

The department of pathology has been without a permanent executive since Dr. Alvin J. Cox, Jr., professor of pathology, resigned in 1964 after 23 years of active leadership to devote time to research in dermatology.

Dr. Korn was graduated with honors from Harvard University in 1954 and from the Harvard Medical School in 1959, and received his training in pathology at the Massachusetts General Hospital in Boston. Subsequently, he taught at Harvard Medical School.

In 1961, Dr. Korn became research associate in the Laboratory of Biochemistry and Metabolism of the National Institute of Arthritis and Metabolic Diseases advancing to his present post. He is a member of the American Society for Cell Biology, American Society for Experimental Pathology, and International Academy of Pathology. Among his honors, Dr. Korn includes the Detur Prize and the Soma Weiss Prize.

Dr. and Mrs. Korn are the parents of three children.

STANFORD--Dr. F. Frank Zboralske has been appointed associate professor of radiology and head of the division of diagnostic roentgenology at the Stanford University School of Medicine.

The announcement was made today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school.

He succeeds Dr. Herbert L. Abrams who has been named professor and chairman of the department of diagnostic roentgenology at Harvard Medical School.

Dr. Zboralske, who will assume his new position next month, has been an assistant professor of radiology at the University of California Medical Center in San Francisco since 1965. At the medical center he also was director of the experimental radiology laboratory, chief of the section of gastrointestinal radiology, and co-director of a research training grant in diagnostic radiology from the National Institutes of Health.

Prior to his association with the UC Medical Center, Dr. Zboralske was an instructor and assistant professor of radiology at Marquette University School of Medicine in Milwaukee, Wis., and served as a radiologist at Milwaukee County General Hospital.

Dr. Zboralske was awarded his M.D. degree in 1958 from Marquette University School of Medicine. He was named as a James Picker Foundation scholar in radiological research in 1962.

Dr. and Mrs. Zboralske have four children.

STANFORD--Aided by computers, Stanford University medical researchers can now measure the slightest hearing loss in the youngest infants.

The disclosure was made today by Dr. F. Blair Simmons, associate professor and head of the Division of Otolaryngology, as he described how a hearing test via a computer helped in the adoption of a six-month-old infant by a Redwood City, Calif. couple.

Mr. and Mrs. John P. Watney were anxious to adopt a baby named Jacqueline. But a serious question about the baby's hearing ability was raised casting a shadow on their plans.

"The usual hearing tests were inconclusive, as is often the case with young infants," related Dr. Simmons. "Until recently, the prospective parents, the adoption agency, and the physicians simply had to wait until a baby grew older before a health report, required before any adoption, could be completed."

Jacqueline was brought to Stanford's Ear, Nose and Throat Clinic one day and slept through her test period. Dr. Simmons said within an hour it was established that her hearing acuity was within normal limits, a happy ending for all concerned.

The new technique, called EEG audiometry, uses information gained from picking up the brain's electrical responses to sound, Dr. Simmons explained. With the baby mildly sedated and asleep, EEG-type electrodes are pasted on the infant's scalp to monitor brain electrical activity before, during and after the test is given.

Although use of the EEG (electroencephalograph) for hearing tests dates back to more than 35 years, the technique has seldom been employed in infants because their electrical responses to sound are indistinguishable from the random brain noise.

-MORE-

It is here where the computer goes to work. In a soundproof room, Dr. Simmons, Dr. F. Mark Rafaty, a resident in otolaryngology and one of the chief organizers of the project, and their associates take repeated samplings of the patient's brain electrical activity under conditions of absolute calm and also under auditory stimulation provided by a series of clicks of very low intensity fed through a loudspeaker.

"During this period," said Dr. Simmons, "the memory of the computer stores the auditory signals presented to it, remembering and displaying mathematically the sum of voltages in sequence. The unwanted background noise, being random in occurrence is thus cancelled out while the evoked responses, occurring precisely time-locked to the delivery of stimulus, are exaggerated."

Because the technique requires no verbal involvement, it can be used to test hearing loss in brain-damaged or mentally retarded children, stroke victims, and even in persons who deliberately try to fake a hearing loss, he said.

A research tool for many years, the technique has only recently been applied to clinical problems, Dr. Simmons said.

The work is supported by grants from the National Institutes of Health.

STANFORD---Dr. Angelos Dellaporta has been appointed associate professor of surgery and head of the division of ophthalmology at Stanford University School of Medicine.

The announcement was made today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school.

He succeeds Dr. Frank C. Winter, who has been acting head of the division since 1959. Dr. Winter is a practicing ophthalmologist in Palo Alto, and clinical associate professor of surgery at Stanford.

Dr. Dellaporta has been associated with the School of Medicine since 1957 when he joined the faculty as a research associate and instructor in the Division of Ophthalmology. In 1961 he was appointed as assistant clinical professor and in 1966 as an associate clinical professor in the division.

Prior to joining the Stanford faculty, Dr. Dellaporta was director of research at Buffalo (New York) Eye Bank and Research Laboratory at the University of Buffalo for four years. He also spent six months on a special fellowship at the Eye Institute of Columbia University.

Dr. Dellaporta, a native of Greece, received his M.D. degree in 1939 from the University of Freiburg, Germany. In 1950 he received a Doctor of Science degree in ophthalmology from the University of Vienna (Austria) where he was also senior attending physician in the 1st Eye Department from 1943 to 1952.

Dr. and Mrs. Dellaporta and their four children live in Atherton.

STANFORD -- The problems of children with chronic disease or disability will be studied intensively for the next three years at Stanford University School of Medicine under a research grant from The John A. Hartford Foundation, Inc., of New York.

Announcement of the $244,175 award for investigations of hereditary and developmental aspects of disease involving mesenchymal tissue was made jointly by Ralph W. Burger, Foundation president, and Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine. The mesenchyme, a structure of connective tissue, regulates the flow of nutrients, metabolites, hormones and drugs.

The research team of physicians and biochemists will be headed by Dr. Norman Kretchmer, professor and executive head of the Department of Pediatrics, and Dr. William van B. Robertson, professor of biochemistry in the Department of Pediatrics, co-principal investigators. The three-year study will begin September 1.

Others cooperating in this research are Dr. Norman J. Sissman, associate professor of pediatrics, Dr. Vincent A. Marinkovich, assistant professor of pediatrics, Dr. John J. Miller III, clinical instructor in pediatrics, Dr. Merton R. Bernfield, assistant professor of pediatrics, Dr. Noreen Eldredge, research associate, and Dr. Daisy Lee, research fellow.

"A significant fraction of the chronic diseases or disabilities of children involve tissues of mesenchymal origin," Dr. Kretchmer said. "Our understanding of this complex structure and how it is changed in disease will determine the extent to which we are able to interfere therapeutically to treat or prevent disability."

Experimental programs have already been developed to find more effective and more economical ways of handling the problems of care and adjustment presented by children with chronic disability, Dr. Kretchmer pointed out.

-more-

"These are certainly necessary," he said, "but the real breakthroughs in treatment and prevention will come only when attacks are directed at specific disease processes. This means we have to gain a greater knowledge of the tissue constituents involved and their interactions."

Among the diseases to be studied are:

--juvenile rheumatoid arthritis, a crippling disease of joints. Neither the cause nor the fundamental nature of the disorder is known, nor is definitive therapy available.

--hereditary abnormalities such as gargoylism, osteogenesis imperfecta and achondroplasias. In all of these, genetic defects in the metabolism of a chemical component of connective tissue lead to severe crippling often associated with mental deficiency. Although any one of these diseases is relatively rare, together they represent a significant percentage of birth defects.

--congenital heart disease. The Children's Bureau has reported that 25,000 babies are born in the United States each year with congenital heart disease and of these about 7,000 die in the first year of life. The identification of the mechanisms of normal cardiac development using quantitative techniques is necessary for further progress in this area.

--asthma, a respiratory disease affecting more than 100,000 children in the United States. Not only does the chronic stress of impaired breathing lead to permanent damage of the pulmonary mesenchyme, but it now appears that interactions between immune organisms and a connective tissue may be involved in the acute attack.

The major portion of this research will be carried out at the Stanford Children's Convalescent Hospital, the chronic disease service of the Department of Pediatrics.

The study is an outgrowth of previous research in this general area of medicine supported by the Hartford Foundation since 1960 with grants totaling more than $700,000.

STANFORD--Investigators from the Stanford University School of Medicine and the California State Department of Public Health have linked the virus that causes common measles to an invariably fatal form of encephalitis that affects as many as 200 children and young adults in the United States each year.

Research findings using modern techniques of electron microscopy and immunology point toward the measles virus as the cause of the disease, the investigators believe. Their studies have revealed the presence of viral particles within the nuclei of brain cells. Evidence pointing to measles has also come from other laboratories around the world. But the scientists acknowledge that final proof still is lacking until the virus itself can be successfully isolated in victims of the rare disease.

The disease is commonly known to physicians as Dawson's subacute inclusion-body encephalitis, after its discovery, in 1933, by Dr. James Dawson, now of the University of Minnesota. It hits young persons between 5 and 20. Symptoms include involuntary movements of the limbs, and profound mental changes. The blood of the victims also shows an unusually high prevalence of antibodies to the measles virus.

The Stanford and Berkeley investigators have postulated that the disease may be a consequence of a latent or chronic infection with a measles virus that has been reactivated. If their theory is correct, viruses from other diseases left over in the body may be the cause of some of man's most puzzling ailments. Among the ailments are multiple sclerosis, amyotrophic lateral sclerosis (Lou Gehrig's Disease) and certain leukemias.

These findings have been reported by Drs. Robert M. Herndon, John M. Freeman, Guy McKhann and Lucien J. Rubinstein of Stanford University, and Drs. Edwin H. Lennette and Robert L. Magoffin of the Viral Rickettsial Disease Laboratory at Berkeley. They were presented in part at the American Pediatric Society meetings earlier this year, in The Lancet, a British medical journal, and at a special conference held recently by the National Institute of Neurological Diseases and Blindness at Bethesda, Md.

-MORE-

The patients studied by the California group have all had measles in the past. The initial measles infection was usually uncomplicated and had occurred as many as eight years before the appearance of Dawson's encephalitis. All patients have had significantly higher levels of antibodies to the measles virus than do normal individuals, the investigators said.

In two children studied, gradual deterioration of personality and intellect spanned a nine-month and a one-year period, and was followed by more rapid and ominous deterioration for about a month. Both patients also had abnormal EEG (brain wave) patterns. Recently two more cases have been brought to the investigators' attention. One of these was "discovered early by an especially astute pediatrician," who had read of the earlier cases.

He linked minor personality changes, some loss of intellect, and muscle spasms with EEG abnormalities and referred the child to the Palo Alto group for study and therapy. "She is the least severely affected and still functioning child," the researchers said.

The Stanford physicians are treating the disease with antiviral drugs. Although they have been cautious to point out that treatment is "highly experimental," results so far are promising.

In 1964 another group of Stanford researchers (Drs. Rubinstein, Lloyd Silverman, and Carlton E. Schwerdt) successfully demonstrated viral organisms to be responsible for a rare degenerative and fatal disease in adults, called progressive multifocal leucoencephalopathy. Identical findings were reported simultaneously by a group of researchers at the University of Wisconsin. The condition results from the replication of a hitherto unsuspected viral agent in the nuclei of brain cells responsible for the formation and maintenance of nerve fiber sheaths.

Dr. Rubinstein, a neuropathologist, is professor and acting head of the Department of Pathology at Stanford. His associates include members of the Division of Neurology, and the Departments of Medicine, Pediatrics and Medical Microbiology. Their line of investigation has included electron microscope studies of brain biopsies from selected patients, to determine their fine structure and biochemical changes.

An important purpose of these studies is also to isolate and culture the suspected viruses and to develop rational and effective methods of treatment, Dr. Rubinstein said.

STANFORD--A two-year planning grant has been awarded to the Stanford University School of Medicine by the National Institutes of Health to develop a cooperative medical program for improving the level of diagnosis and treatment of heart disease, cancer, stroke and related diseases.

The planning studies will serve to define the medical school's role as a coordinator of health agencies in helping community physicians and other health workers make the most effective use of scientific knowledge for the benefit of patients. The grant will be administered through the California Committee on Regional Medical Programs.

One important aspect of the study will be to determine how cooperative medical programs related to heart disease, cancer and stroke might optimally be developed in the area for which Stanford University School of Medicine has primary responsibility for coordination. This area includes the San Francisco Peninsula and Alameda, Monterey, Merced, Santa Cruz, Stanislaus, and Tuolumne Counties.

The announcement, made jointly by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, and Dr. Robert Q. Marston, associate director of NIH and director of the Division of Regional Medical Programs, said that the grant for the first year is in the amount of $294,495. It is expected that the two-year planning effort will be funded with a total of $586,000.

A citizens' advisory group representing industry, the health professions, and the public will be active in assisting the Stanford faculty. They will work to put together a broad picture of health activities in the eight-county area in an attempt to describe the conditions under which the health services are delivered to patients.

According to Dr. Glaser, Stanford's role will be primarily educational, aimed at improving patient services throughout the geographical area. These may include Stanford-based educational programs for subspecialties covered by the heart, cancer, stroke legislation in which serious manpower shortages exist; continuing education, including specific demonstration programs of patient care for physicians in private practice; and coordination of services between a centralized training, research, and care facility at Stanford and local patient care centers from which patients are ordinarily referred.

Other programs to be considered include:

--A centralized facility to educate both medical and paramedical personnel in coronary care.

-MORE-

--The rapid dissemination of information regarding monitoring of heart patients and the application of new treatment concepts to patients in both present coronary care facilities and those which will be built in the future.

--A diagnostic center to evaluate patients for predisposing factors of heart disease.

--A central organization with clinical, biochemical, genetic, and computer-oriented personnel to work in a program of mass prevention of coronary heart disease.

In addition, the Stanford faculty will direct its attention to present diagnostic and treatment practices for cancer, and stroke patients, the amount of continuing education available to community physicians about cancer, stroke and related disabilities, and the facilities needed to improve neurological care in all major communities.

Editors: Copies of STANFORD M.D. are available on request.

STANFORD--The physician who substitutes friendliness for knowledge in treating patients is in reality denying the critical assistance patients need, a Stanford University physician and medical educator said today.

"The average physician of the future must clearly embody both characteristics, because his heightened powers will deepen and make even more important the relationship between him and the patient," said Dr. Halsted R. Holman.

Dr. Holman, Guggenhime professor of medicine and head of the Department of Medicine at the Stanford University School of Medicine, presented his views in the October issue of STANFORD M.D., the quarterly magazine of the Stanford Medical Alumni Association.

As the complexity of medicine increases and the intrusion of technology becomes greater, Dr. Holman writes, it is commonplace for some people to see a contradiction between science and medicine and to yearn for the return to a simpler situation of nonscientific medicine. In particular, science is viewed as being cold and impersonal and the same characteristics are attributed to scientific medicine.

"The conceptual and technical aspects of medicine are distinct from the compassion and sensitivity required of the physician in dealing with the discomfort, fears and worries of the patient," Dr. Holman argues. "There have always been different types of physicians, some unsympathetic and cold and some warm and understanding. To ascribe to the science of medicine the human shortcomings of certain physicians is quite to miss the point."

Because of the rapid evolution of knowledge, the physician of the future, according to Dr. Holman "must be able to comprehend and interpret scientific advance as it occurs, reorganize his concepts of medicine, and institute new practices in caring for the patient virtually continuously." Dr. Holman cites these examples:

--There are now drugs which affect the function of the brain, though physicians barely understand their mechanism of action. Physicians are able, however, to study brain function at the cellular level. It is possible that in a short time physicians will possess substantial capacity to alter brain function directly.

-MORE-

--Transplantation of organs has long been technically feasible. It is probable that physicians will soon be able to inhibit the immune response of a potential recipient solely to the transplantation antigens of the potential donor and consequently be able to graft organs which are not rejected.

--Physicians, through use of miniaturized sensing devices and computation techniques, can now make exquisite physiological measurements on man. They are no longer, therefore, at the mercy of nature in dealing with the individual in shock or in whom a major organ such as the heart or lung has been temporarily incapacitated. It is possible now to monitor such patients precisely, determine instantly the effects of drugs, and permit recovery in a way hitherto impossible. But very sophisticated knowledge is required of the physician who wishes to accomplish this end.

--It is now clear that certain hormones act by influencing the expression of genes within the cell. It will not be long presumably until physicians can mimic nature and perhaps suppress or activate certain types of genes at will, resulting in substantial changes in the body of the patient.

--In the future, the treatment of malignancies may not be restricted to radiotherapy or extirpation but may involve the use of chemicals which will alter the growth patterns of cells and hence, properly used, correct the uncontrolled growth of the malignant tissue.

"Compared to what we can do for patients today, the therapeutic armamentarium of the physician perhaps merely a decade from now may become infinitely larger and more complex," Dr. Holman said. "Yet a decade from now is but the time our current students will be in the early stages of their practice."

These developments place major demands upon the medical educator and increased service obligations upon the practicing physician. To share in the growth of medicine and partake of its intellectual rewards, the practicing physician must have time to think, read and exchange ideas with his colleagues, according to Dr. Holman. This may require changes in the patterns of practice and certainly more profound relationships with his colleagues in medical schools and medical centers. Occasional courses and conferences will not suffice.

"The physician who substitutes friendliness toward the patient for knowledge which might decisively help the patient and which the physician is either unwilling or unable to obtain, is in reality denying the patient the critical assistance which he needs," Dr. Holman said.

STANFORD--Dr. Robert J. Glaser, vice-president for medical affairs and dean of Stanford University School of Medicine, is the new president-elect of the Association of American Medical Colleges.

His election was announced today in New York where the Association is holding its 78th annual meeting. Dr. Glaser will assume his duties in October 1968.

Dr. Glaser is the third Stanford medical school dean to serve as president of the Association. The first was Dr. Ray Lyman Wilbur in 1924-25 and the second Dr. Loren "Yank" Chandler who served in 1941-42.

A graduate of Harvard College and the Harvard Medical School, Dr. Glaser has been a leading progressive force in the development of medical education. He has always had strong ideas about the general practice of medicine, deeming exceedingly important the "concept of integrating the efforts of various disciplines into better patient care."

An outspoken critic of hospital designs and current patterns of staff utilization and equipment, Dr. Glaser has proposed an examination of the present system, with emphasis on the application of modern managerial techniques and engineering technology to achieve optimum use of hospitals and cut cost to the patient.

Dr. Glaser assumed his present post at Stanford in July 1965. Prior to this, he was president of Affiliated Hospitals Center and professor of social medicine at Harvard Medical School, where he completed the preliminary steps toward affecting the merger of six Harvard teaching hospitals into a $50-million medical school-hospital complex. From 1957 to 1963, he was vice-president for medical affairs and dean of the University of Colorado School of Medicine, where he played an instrumental part in the completion of its medical center complex.

A man of varied interests, Dr. Glaser has also been concerned with research in the area of streptococcal infections and rheumatic fever.

STANFORD--Dr. Robert H. Alway, professor of pediatrics and former dean of Stanford University School of Medicine, has taken a year's leave of absence from the faculty to direct a study in Palo Alto of sub-baccalaureate medical laboratory technical personnel training and certification.

The study, financed by the Carnegie Corporation of New York, will also include the areas of curricula, facilities, accreditation of schools training such personnel, and related areas affecting both present and future performance of clinical laboratories.

###

STANFORD--Dr. Leland B. Blanchard, clinical faculty member of the Stanford University School of Medicine, has been appointed assistant director of the department of undergraduate medical education of the American Medical Association.

He will also serve as secretary of the Committee on Family Practice of the AMA Council on Medical Education.

Among other duties, Dr. Blanchard will be involved in developing plans for implementing the recommendations of the AMA Ad Hoc Committee on Education for Family Practice. The responsibility for planning the implementation of the recommendations has been assigned to the Committee on Family Practice.

Dr. Blanchard is a 1937 graduate of the Stanford Medical School where he holds an appointment as clinical assistant professor of medicine. He also maintains a private family practice in San Jose.

This year, Dr. Blanchard is serving as general chairman for the 1967-68 medical alumni Annual Fund campaign.

STANFORD - Dr. Donald S. Fredrickson, director of the National Heart Institute at the National Institutes of Health, will deliver the fourth John Kent Lewis Lecture at Stanford University School of Medicine Oct. 31.

He will speak on "Fat Transport in Man: Mechanisms and Mutations" at 4:45 p.m. in Room M106.

Dr. Fredrickson is an internationally recognized authority on fat transport in the circulation and on the diseases of lipid metabolism. As a senior research staff member of the Laboratory of Cellular Physiology and Metabolism, he participated in a series of studies from 1955-61 that resulted in fundamental contributions to scientific knowledge of mechanisms whereby fats and fatlike substances are transported, synthesized, and broken down by the body.

These studies also investigated the effectiveness and mode of action of various drugs that reduce blood levels of cholesterol and other lipids.

Subsequently, first with the Laboratory of Metabolism, then as chief of the Laboratory of Molecular Diseases, Dr. Fredrickson conducted and directed laboratory and clinical research on the structure of plasma lipoproteins, their role in fat transport, and on genetic factors that regulate lipoprotein metabolism. His studies of hereditary diseases of fat storage and metabolism included discovery of the lipoprotein deficiency state, Tangier disease, and establishment of its mode of inheritance.

In 1955, Dr. Fredrickson and his colleagues introduced a new system for using plasma lipoprotein patterns to identify and classify excess of blood cholesterol and other fats. With it they have demonstrated several new syndromes not previously recognized as separate diseases. This system is now in use in a number of laboratories in this country and abroad.

Dr. Fredrickson is a native of Canon City, Colo. He received the A.B. in 1946 and the M.D. degree in 1949 from the University of Michigan and did postgraduate work at the Peter Bent Brigham Hospital, the Massachusetts General Hospital, and the Harvard Medical School before joining the NIH scientific staff as a clinical associate in 1953. Prior to assuming his present position in 1966, Dr. Fredrickson served five years as clinical director for the National Heart Institute, with responsibility for all research involving patients and normal volunteers.

In addition to his duties as director, Dr. Fredrickson remains chief of the Laboratory of Molecular Diseases where he continues his research work.

Dr. Fredrickson's lecture is dedicated to the memory of Dr. John Kent Lewis, professor of medicine and chief of the Stanford Medical Service in San Francisco who died in 1961. Dr. Lewis, with Stanford professors A.W. Hewlett and George D. Barnett, published some of the early work on vascular sounds, exercise, and respiration.

STANFORD--A new experimental training program in investigative medicine will be initiated by the Stanford University School of Medicine.

Announcement of the program, which will be funded by a $143,000 grant from the National Institutes of Health, was made today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school.

Dr. Halsted R. Holman, Guggenhime professor and executive head of the Department of Medicine, will direct the program for medical students and postdoctoral fellows. He will be assisted by Dr. Thomas Merigan, associate professor of medicine and head of the Division of Infectious Diseases, and Dr. Hugh McDevitt, assistant professor of medicine.

"Investigative medicine increasingly requires a proficiency of clinical analysis and management of individual patients and a detailed, imaginative use of experimental biological techniques in studying problems presented by the patient," says Dr. Holman.

"It is our hope," he notes "that the new program will meet this requirement--training physicians for careers in academic internal medicine and enabling them to function as investigators, teachers, and clinical specialists."

Currently, most physicians who ultimately undertake an academic career obtain both their clinical and investigative training, requiring from five to ten years, after graduation from medical school. It is hoped that the new training program will permit a significant number of students to develop independent investigative capabilities while still medical students, thus eliminating several years of additional training.

-MORE-

The five-year curriculum of the Stanford Medical School is particularly adaptive to the objectives of the new training program, Dr. Holman points out. Presently half of the three-year preclinical science training is free for elective work as are 12 months of the last two clinical years.

"This curriculum attracts many students already interested in research and contemplating an academic career. Members of the faculty have found that undergraduate medical students are often fully as capable and dedicated to rigorous investigative work as their postgraduate colleagues," Dr. Holman says.

"By making students an integral part of this training program in which they will experience both laboratory and, to some extent, clinical activities, we hope to identify and develop trainees at an early stage in their medical education and and simultaneously provide them with a broad training experience.

For postdoctoral trainees, the program will seek to develop an independent investigative capability while providing some continuous clinical experience in depth.

"At the present time, post graduate physicians considering a career in investigative medicine face a major dilemma, namely, that training in investigation is usually divorced from training in clinical medicine in terms of both location and teachers," Dr. Holman says.

"The proposed program seeks to resolve this problem by combining in one program the faculty, fellows and students of four divisions of the Department of Medicine (infectious diseases, oncology, immunology, and human genetics) whose clinical and investigative interest coalesce and complement one another. At any one time, some members of each division will be free of most clinical obligations. Fellows and students will be in continuous geographical and intellectual contact with one another and the faculty."

STANFORD--Dr. Harry R. Lusignan, Monterey physician, has been named area chairman for the 1967-68 Advance Gifts Personal Solicitation Program for the Stanford University School of Medicine.

With research grants, tuition and student fees meeting part of its operating budget, the Stanford Medical School must count on endowment earnings and private gifts for a significant share of its operating costs. The solicitation for the School is part of the Stanford Annual Fund, started 30 years ago to help provide such support.

This year the Stanford Annual Fund seeks to raise $1.8 million in unrestricted gifts to the University, including Medical School support.

Stanford medical alumni will be solicited personally in the Monterey area during the six-week campaign which begins Thursday (OCT. 12).

Dr. Lusignan, a pediatrician, graduated from the Stanford Medical School in 1929. He has two sons.

STANFORD--Human reproductive physiology, contraceptives, and the world population problem are among the topics being discussed in a unique course offered this fall to biology teachers of Santa Clara County.

The course, Human Reproductive Physiology and Problems of Population Control, is being offered by the department of pharmacology at Stanford University School of Medicine in association with other University departments and the Santa Clara Valley Science Teachers Association (SCVSTA). Members of the departments of gynecology and obstetrics, and biology at Stanford will participate in the course.

Dr. Sumner M. Kalman, professor of pharmacology who spearheaded organization of the course, stresses that the course is being offered as a public service by the Medical School.

"It will enable the teachers to answer questions and present relevant material in their classes with greater knowledge of a most important subject area," he says.

Larry Flammer of San Jose, who is handling registration and attendance for the course for the SCVSTA, notes that there has been a great need for a course encompassing the planned subject matter.

"Although each teacher will incorporate the course work into his own teaching in various ways, all will be provided with background information in depth on material which they can teach with some degree of authority," he says.

Flammer and Dr. Kalman held preliminary discussions on the possibilities of the workshop seminar last spring. Following a highly favorable survey of area science teachers for interest in the proposed course, final plans were made.

The topic of Monday night's (OCT. 2) opening lecture by Stanford biology professor, Paul R. Ehrlich, was "Biology of Population Growth." Future subjects to be covered include venereal diseases and its prevention and treatment, abortion, and heterosexual relationships among teenagers.

More than 70 teachers are expected to attend the classes which are being held on Monday evenings at 7:30 p.m. in Room M114 of the Medical School. The two-hour classes will be held through Dec. 4. ### ---Mailed October 3, 1967

STANFORD--Study of the body's immune system, quietly but steadily growing in the past decade, has suddenly burst forth as a scientific field with important clinical application in the treatment of patients.

Immunology is one bridge between the basic and clinical sciences that promises an ever-increasing impact on both treatment and research in areas such as cancer and the rheumatic diseases.

In accord with these developments, Stanford University School of Medicine, in conjunction with the Palo Alto-Stanford Hospital, has established its first Clinical Immunology Laboratory under the supervision of Dr. Gordon Sharp, assistant professor of medicine.

"New knowledge in immunology has increased the number and reliability of our tests for immunologic abnormalities," Dr. Sharp says. "We are currently conducting four basic tests as well as some promising research work."

One of two tests which relates most specifically to the rheumatic diseases, has proved very useful in diagnosing systemic lupus erythematosus (SLE), a serious inflammatory disorder affecting many organ systems of the body, commonly known as "lupus."

"It has been known for some time that patients with lupus have a factor in their serum which, in a test situation, results in a peculiar reaction where degenerating cell nuclei are ingested by white blood cells. This is known as the LE cell phenomenon."

The test for diagnosis of lupus now being done in the new Stanford laboratory which involves a technique called complement fixation, grew out of research on the mechanism of the LE cell phenomenon by Dr. Halsted R. Holman, Guggenhime professor and executive head of the Department of Medicine. Studies by Dr. Holman and others showed that the LE factor was only one of a whole spectrum of anti-nuclear factors, antibodies directed against various portions of the cell nucleus, that are found in the blood serum of patients with lupus.

"The test we are using," declares Dr. Sharp, "will reveal cases of lupus that might have been missed by the standard LE cell test being done in many other laboratories. Not only will it detect almost all of the anti-nuclear factors, but it is highly specific, having very infrequent positive findings in normal individuals or patients with unrelated diseases."

-MORE-

"Use of this test has been found by the hospital and the medical community to be so successful in the diagnosis of lupus that increased demand and use were partially responsible for the establishment of the new laboratory," according to Dr. Sharp.

The other test used in the diagnosis of rheumatic diseases measures the level of serum gamma globulin or antibody-containing fraction of the blood.

"An increase or decrease of the gamma globulin level has certain diagnostic usefulness," Dr. Sharp says. "Those patients with a low level are often susceptible to infections and may benefit by receiving gamma globulin injections. Lupus patients and others with certain rheumatic diseases characteristically have a high gamma globulin level which usually returns to normal as they respond to therapy."

The immunology laboratory has also been performing two other tests: immunoelectrophoresis (IEP) and thyroid antibody.

The IEP test aids in detecting cases of a form of cancer called multiple-myeloma which is a plasma cell tumor frequently associated with a large amount of abnormal circulating protein.

"By IEP we can frequently detect and characterize this abnormal protein and thereby make an early diagnosis of the presence of a tumor," Dr. Sharp points out. "Often this protein might not have been detected by the standard laboratory tests which have been performed over a number of years."

Use of the thyroid antibody test has grown out of a research interest in experimental thyroiditis, which is an animal model of an inflammatory disease of the human thyroid gland, according to Dr. Sharp. "We are now testing for thyroid antibodies in patients with thyroiditis and the finding of such antibodies assists in diagnosing the disease.

"In addition to our regular testing," Dr. Sharp notes, "we have been conducting studies in the laboratory to improve and enlarge the services we can offer in the area of immunology."

"We have developed another anti-nuclear test which involves a technique called hemagglutination that is more sensitive than the one presently being used. It specifically measures the antibody to DNA (deoxyribonucleic acid), one constituent of the cell nucleus. The presence of this antibody seems to have a very close correlation with the seriousness of the lupus disease."

Dr. Sharp also points out that the new test has great specificity. "We have examined over 200 control patients and only rarely have found a positive test in normal people or patients with other diseases.

Although studies on the new test are still in the developmental stage, we hope to be able to add it soon to the clinical tests which are available, he says.

STANFORD--Two leaders in the field of medicine from Stanford University have been named by the National Academy of Sciences to a Board of Medicine to find ways of speeding the benefits of medical research and practice to the public.

They are Dr. Robert J. Glaser, vice-president for medical affairs and dean of Stanford University School of Medicine, and Dr. Dwight L. Wilbur, clinical professor of medicine and president-elect of the American Medical Association.

Dr. Glaser, who last month was elected president of the Association of American Medical Colleges, and Dr. Wilbur join 19 other board members from both medical and non-medical fields.

Formation of the high-level group represents growing concern by the academy, the medical profession and Federal agencies that the increase in biomedical knowledge is outstripping its application to "critical human needs," Dr. Frederick Seitz, the academy's president said.

Questions to be considered by the board include the ethical and legal implications of experimenting with human beings; the role of medical schools and other biomedical institutions in attacking rural and urban slum problems; how to improve the quality and delivery of medical care; how to shorten the time between the acquisition of new knowledge and its application; and how medical knowledge is used, refreshed and taught.

Dr. Seitz said that the board had been asked to "range broadly in identifying urgent problems, to be imaginative in seeking solutions, and innovative in recommending public policy."

Chairman of the new Board of Medicine will be Dr. Walsh McDermott, professor and head of the department of public health at Cornell University Medical College.

FOR PM RELEASE MONDAY, NOVEMBER 20, 1967

STANFORD--A Stanford University cardiovascular surgeon said today that some of the technical problems standing in the way of transplanting a healthy heart to replace a diseased one have been solved and "the way is clear for human trial."

Dr. Norman E. Shumway, professor and head of the division of cardiovascular surgery at Stanford University School of Medicine, expressed this view in an interview appearing in the November 20 issue of the Journal of the American Medical Association.

"We have achieved a degree of experience with heart transplantation in the laboratory and we feel confident we can take appropriate care of the patient with a cardiac transplant," Dr. Shumway said.

"Although animal work should and will continue, we are nonetheless at the threshhold of clinical application," he added.

Making such heart transplant possible requires that an ideal donor and recipient be available at the same time. "Thus far, the two requirements have not coincided," Dr. Shumway said.

In fact the major problem, the pioneer surgeon said, is choosing an appropriate recipient for a heart transplant. "Even in the patient with advanced coronary artery disease, who is incapacitated to a great degree, the surgeon would hesitate to remove an organ which is, after all, supporting the life of that individual," he said.

He predicted that the first clinical transplant in human patients will probably be confined to recipients who are unable to sustain their own circulation. The most likely candidate would be a patient undergoing open-heart surgery whose normal heart beat cannot be restored when he is taken off the heart-lung machine.

Other possible recipients are children with congenital abnormalities for which there is no corrective surgical therapy and for whom the various life-sustaining measures available are not satisfactory.

Dr. Shumway said the ideal donor would obviously be a relatively young patient dying of causes unconnected with heart disease.

Experimental evidence shows that if the heart can be removed from the donor within a half hour after death it can be resuscitated without suffering damage, Dr. Shumway explained. The time span during which a donor heart remains available for transplantation can be lengthened somewhat by immersing the heart in cold saline solution. Dog hearts have been successfully transplanted at Stanford after immersion in cold saline up to seven hours.

-MORE-

Dr. Shumway and his colleagues also have implanted the dog heart in a temporary host for up to four days before final transplantation in a recipient.

Resuscitated dog cadaver hearts have been maintained by a heart-lung machine for periods of up to 30 hours. Techniques for extended preservation of whole organs, however, are rudimentary.

"It may be possible to maintain a heart for short periods by cross-circulation with a third party or with a heart-lung preparation, but at the moment we are depending upon the coincident situation in which the donor and recipient are immediately available," Dr. Shumway said.

This means that as long as heart transplantation in the human is confined to emergency situations, its use will depend upon the chance availability of a suitable donor at the time of critical need. The situation differs from that of a patient awaiting a cadaver kidney transplant who can be maintained for a prolonged period by an artificial kidney.

Heart transplantation then is not likely to receive widespread use until methods are found for long-term preservation of the organ or until experience indicates that it can be used as an elective as well as an emergency procedure, Dr. Shumway commented.

He said the surgical technique of transplantation has been thoroughly worked out in the laboratory and technical difficulties are not anticipated in clinical application. In fact, transplantation in the human probably will be less difficult technically than it is in the dog, where the fragile nature of the canine organ presents a problem and is a challenge to any surgeon's skill.

Dr. Shumway added the rejection reaction of the recipient to a heart transplant is expected to be the same as that associated with kidney transplants. However, laboratory findings suggest that a heart transplant patient might not be able to tolerate the level of drug therapy used to treat kidney transplant patients.

This has led to an extensive search for an indicator of cardiac rejection in the hope that drug dosage could be adjusted to afford maximum protection with minimum use. It was found that a reliable indicator of rejection is provided by the electrocardiogram. Using the electrocardiogram as a guide, Dr. Shumway and his associates, have placed dogs with transplanted hearts on schedules in which the drugs were administered only during the rejection crisis.

"This has worked very well and enabled us to get our first survivals into durations of months instead of weeks," Dr. Shumway said. The longest dog survival has been one year.

FOR IMMEDIATE RELEASE

STANFORD-A team of Stanford students preparing a new plan for Concord will meet with city officials, Chamber of Commerce members, and interested residents Tuesday at 8 p.m. Nov. 21, in the Concord City Council chambers.

It will be the first formal presentation by the students participating in the current "Concord 70" project. Another presentation will be made in March and a final presentation in June.

The Stanford team is made up of 20 students in architecture, law, engineering, business, communications, geology and history. The plan will emphasize the downtown area and will pay particular attention to the potential of BART, the lakes, the plaza area, the civic center and the Sun Valley and Park and Shop centers.

The students in charge of Tuesday's presentation are Robert Basile, 192 Hudson River Road, Waterford, N.Y.; Sam Sperry, Galesburg, Ill., Robert Cox, 5858 Pennswood Ave., Lakewood Ted Vian, Stanford, and Joe Ritchey, 1088 Los Gatos Hwy, Santa Cruz, Calif.

Tuesday's meeting will be a program presentation, stressing what students intend to do more than what they have done, and procedures more than proposals. Members of the audience will be asked to respond to a questionnaire probing their attitudes toward planning in Concord.

During October, the students spent a weekend in Concord staying at the Concord Inn and collecting information and impressions of Concord. They were guests of Bart Lytton, board chairman of Lytton Savings and Loan Association and a guest professor for the course. They also met with members of a Chamber of Commerce committee serving as liason between the students and Concord.

Between presentations, the students will post progress reports of the project on a contemporary kiosk which they have erected in the plaza near Willow Pass Rd.

Editors: The press is invited to hear Dr. Wilbur's remarks. Text will not be available in advance.

STANFORD--Dr. Dwight L. Wilbur, president-elect of the American Medical Association, will be principal speaker at the Stanford Medical Alumni Association's annual get-together Friday (NOV. 17).

Dr. Wilbur will speak on "Medicine and the Government" during the afternoon program to be held at the Cabaña Hotel in Palo Alto.

The new AMA president, who completed his undergraduate work at Stanford in 1923, is a clinical professor of medicine at the medical school. Dr. Wilbur received his M.D. degree from the University of Pennsylvania in 1926 and an M.S. in medicine at the University of Minnesota in 1933. He also was a Fellow and later a consulting physician at the Mayo Clinic before entering private practice in San Francisco in 1937.

Scheduled at 9:45 a.m., following registration and welcoming remarks at the medical school, are combined grand rounds of the clinical departments. A presentation on "Infection in the Impaired Host" by members of the faculty is also planned. This will be followed at 11 a.m. by a presentation on the "Controversies Regarding Diagnosis and Treatment of Coronary Artery Disease."

The ladies' program consists of a guided tour of the Stanford Linear Accelerator Center, leaving the medical school at 9:30 a.m. and returning at noon.

The noon program includes luncheon at 12:30 p.m. for the alumni, wives, faculty and friends at the Cabaña Hotel.

A report on the state of the medical school by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, will lead off the afternoon program at 1:30 p.m. Remarks by Dr. Wilbur will conclude the day's activities.

ADVANCE FOR RELEASE IN AFTERNOON PAPERS WEDNESDAY, NOVEMBER 15.

(ADVANCE) WASHINGTON, D.C.--The incidence of fatal altitude sickness and other problems of exposure to high altitudes will continue to grow as increasing numbers of people live or travel in high altitude areas, a Stanford cardiologist said today.

"Knowledge of symptoms and remedies can prevent disaster," according to Dr. Herbert N. Hultgren, professor of medicine at Stanford University School of Medicine.

Dr. Hultgren presented his views this morning (NOV. 15) at an international conference on man and high altitude being held here this week under sponsorship of the National Academy of Sciences and the Pan American and World Health Organizations.

Dr. Hultgren cited research that he and his colleagues have been conducting since 1958 in the Peruvian mining community of La Oroya, 12,200 feet high in the Andes.

The Peru research project, he said, has revealed that altitude sickness generally involves acute pulmonary edema rather than heart malfunction. Pulmonary edema is the movement of fluid from the blood into the air sacs of the lungs. The fluid acts like a salt-water and egg-white mixture. It froths when the patient breathes and quickly "drowns" him.

The symptoms of pulmonary edema--a persistent cough, shortness of breath after the slightest exertion, a gurgling noise in the chest, coughing up of blood-streaked sputum, and vomiting--usually do not appear until six to 36 hours after arrival in a high-altitude area, Dr. Hultgren said.

These signs resemble those of pneumonia, but without chills or fever. When the danger signals occur, the patient should be quickly brought to lower altitude and given absolute bed rest with oxygen continuously administered. Recovery is usually complete in three days.

-MORE-

"A similar clinical picture is seen in mountaineers," Dr. Hultgren noted, "but because of the frequent unavailability of oxygen and the long time required for evacuation to a lower altitude, the edema may be severe and frequently fatal. Many deaths previously ascribed to pneumonia may have been high-altitude pulmonary edema, uncomplicated by infection.

Acute high-altitude pulmonary edema occurs most frequently in persons who travel within a day or two to elevations of over 9,000 feet, Dr. Hultgren explained. But acclimatized mountain residents who visit a low altitude for one to two weeks and then return to a higher elevation also seem susceptible.

Since this condition can be fatal, Dr. Hultgren offers these words of advice:

-- methods of prevention and treatment should be emphasized to anyone traveling to an altitude of over 9,000 feet. Mountaineers should be especially aware of the syndrome because of the frequent lack of available oxygen and difficulty of prompt removal of the victim to a lower elevation.

-- acclimatized persons returning to high elevations and persons who have had previous attacks of altitude sickness should be informed of preventive measures and methods of treatment.

-- adequate time should be taken in gradual ascent to permit full acclimatization. After arrival at a high altitude area, a period of rest and inactivity for one to two days should be observed.

-- cough, shortness of breath, noisy breathing or blood-streaked sputum are indications of prompt medical attention.

-- all mountaineering parties bivouacking above 10,000 feet should have available emergency oxygen and appropriate tools and spare parts should be provided to utilize additional oxygen if dropped by plane.

Dr. Hultgren said that further studies of the causes of high-altitude pulmonary edema are being pursued in the cardiology laboratory at Stanford since it is apparent that it may have many features in common with pulmonary edema occurring in other conditions of heart disease.

STANFORD--Stanford University School of Medicine has announced the appointment of Dr. Lawrence M. Klainer as assistant dean for clinical affairs and medical director of the Stanford University Clinics.

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine said that Dr. Klainer is expected to "assume a significant role in the hospital planning study currently underway at Stanford and to begin development of experimental approaches to health care that can be tested in our facilities."

Dr. Klainer, who also holds an appointment as assistant professor of medicine and preventive medicine, was commissioned as a U.S. Public Health Service officer in 1963. For the past year he has served as assistant to the dean at Harvard Medical School.

Prior to joining Harvard's administrative staff, Dr. Klainer was a special assistant to Dr. Philip Lee, assistant secretary for health and scientific affairs in the Department of Health, Education and Welfare. While in Washington, D.C., Dr. Klainer, was instrumental in the development of the Health Professions Education section of the White House Conference on Health. He also worked in the areas of international health on joint health programs of the Department of Health, Education and Welfare and the Office of Economic Opportunity.

This spring Dr. Klainer worked on the development of program content for the National Conference on Medical Costs and on the preliminary plans for the National Center for Health Service Research and Development.

In his new position, Dr. Klainer will work closely with the Medical Facilities Planning Group at Stanford on the hospital planning study. His particular interest will be in developing ambulatory care facilities.

Dr. Klainer received his B.A. degree in economics from Antioch College in 1957 and worked for both the U.S. Bureaus of Labor Statistics and Census before entering medical school. He was awarded the M.D. degree in 1961 from Western Reserve University where he was also elected to Alpha Omega Alpha medical honorary society. His internship and residence training was served at the Columbia-Presbyterian Medical Center in New York and at the Massachusetts General Hospital in Boston.

Dr. and Mrs. Klainer and their two daughters are living in Palo Alto.

Science Writers: Following is a statement by Dr. Arthur Kornberg on the significance of viral DNA synthesis that was mailed with earlier story for release Friday, December 15, 1967. There are also some helpful answers to questions addressed by this writer in an interview with Dr. Kornberg this morning.

Spyros Andreopoulos

STATEMENT BY DR. ARTHUR KORNBERG

In our research we try to explain heredity in chemical terms. As you know, heredity resides in our genes. Our genes are, in turn, composed of complex molecules called DNA. About 10 years ago we learned how to synthesize DNA in the test tube with the use of specific cellular enzymes. The DNA we synthesized had the chemical and physical characteristics of natural DNA but it lacked the genetic properties. Recently we have been able to synthesize DNA which has the full genetic activity of natural DNA. In this work we chose one of the simplest creatures, a virus which has only 6 genes. Human cells by comparison have many thousands of genes. Dr. Goulian and I were able to synthesize DNA which had the chemical and physical properties of the DNA obtained from the virus itself.

We asked Dr. Sinsheimer at Caltech to test the biologic activites of our synthetic DNA. He found that the DNA was infective: it was able to enter cells and produce new viruses just as efficiently as DNA from natural viruses. I've mentioned the complexity of DNA molecules. In this case one molecule of viral DNA contains 6,000 building blocks in a very precise sequence; each building block in turn has 35 atoms. The incorrect placement of just one of the 6,000 building blocks can make a DNA molecule biologically inactive. By demonstrating that the synthetic DNA is a fully infective molecule, we can conclude that no such mistakes were made in assembling the 200,000 atoms that make up the DNA molecule synthesized in the test tube.

END OF STATEMENT

QUESTIONS

Q: Have you created life in the test tube?

A: It is really impossible to define the word "life" or "living" to the satisfaction of both laymen and scientists. Most everyone would agree that bacteria are living. But there is a wide difference among the attitudes of scientists as to whether viruses are living. Yet there is no sharp line separating the simplest bacteria and the most complex virus. We know that the viral DNA molecule which we have synthesized can reproduce itself inside a cell and generate new viruses. I believe that it will be possible before too long to circumvent the need for an intact cell for reproduction of the virus. Future research should make it possible to supply all the necessary cellular components. With the reservations I've mentioned, it becomes reasonable to think of the viral DNA as a simple or primitive form of life.

Q: Can you describe the steps involved in the laboratory synthesis of viral DNA?

A: To synthesize any form of DNA, three things are required:

-MORE-

1) Pre-existing DNA to serve as a template to be copied.

2) The four building blocks, or nucleotides, which make up DNA. These are known as A, T, G, and C, the alphabet of the DNA message.

3) An enzyme, called DNA polymerase, which selects the building blocks, according to directions from the DNA template, and then links these building blocks together to form the DNA chain.

To synthesize the viral DNA, one additional component was required. The viral DNA we worked with is circular in form and loses its infectivity when the circle is broken. In synthesizing this viral DNA it was essential that we provide an enzyme which could join the two ends of the chain which had been synthesized. It was crucial to the success of this work that this joining enzyme was discovered just one year ago. As one of several laboratory teams that independently discovered this enzyme, we were able to use it to complete the synthesis of the circular viral DNA.

Q: What do you believe is the significance of this work?

A: I would cite four things:

First-- This work increases the range of our ability to synthesize genetic material. We are reassured that the enzymes and building blocks we use can carry out the error-free synthesis of small chromosomes which contain several genes. We can now look forward to the synthesis of the larger chromosomes of more complex viruses and animal cells.

Secondly--We can produce modified forms of DNA in the test tube by fooling the enzyme into using building blocks which are similar to, but not identical to, the natural ones. Such modified genes when introduced into cells have entirely new properties. Eventually it should be possible to modify the gene in specific ways to produce specific biologic changes.

Thirdly--The polyoma virus produces a variety of cancers in animals. The DNA of this virus is of the same size and complexity as that of the bacterial virus we have been studying. We expect that it should be feasible now to synthesize modified forms of the polyoma viral DNA and determine how to alter its cancer-producing genes.

Fourthly--With advances in genetic chemistry we can look forward to separating and identifying various genes and reproducing them in the test tube. It may be possible then to attach a particular gene to a harmless viral DNA and use this virus as a vehicle for delivering this gene to the cells of a patient. In this way a person may be cured of an hereditary defect.

Q: What is the next step in your research?

A: Our research is taking two general directions:

One direction is to understand in finer chemical detail the structure of the enzyme catalyst, called DNA polymerase, which assembles the DNA chain. This enzyme synthesizes DNA with an accuracy that the finest chemists cannot yet emulate.

-MORE-

If we are to understand how this enzyme works in the cell, in health or disease, during growth or aging, we must first figure out how it works in the simpler and more accessible test tube system.

The other direction of our work is to understand what regulates DNA synthesis in the cell. When growth stops in a mature person, DNA synthesis in his liver cells also stops. However if a portion of the liver is removed at surgery, then DNA synthesis starts up again within 24 hours. Similarly when liver cells turn cancerous, DNA synthesis proceeds rapidly as it does in the young growing liver. We are at a loss to understand the forces that keep liver DNA synthesis in check in the normal adult and what agents provoke DNA synthesis in cancer growth.

Q: What influence will your work have on human evolution?

A: I hope in a way that would have relatively little influence in our lifetime. I say "relatively little" because there is vastly more we can and must do to further human cultural evolution by political and social means. I see the greatest rewards of genetic chemistry to human welfare in the cure of disease and ultimately in a better understanding of human behavior when explained in terms of chemistry.

Science writers: Release date set by the National Academy of Sciences. A press conference has been scheduled with Dr. Arthur Kornberg on Thursday, December 14 at 3:30 p.m. in Room 270, Tresidder Memorial Union on the Stanford campus. Please notify the Stanford Medical Center News Bureau if you plan to attend. Texts of the scientific paper are available on request.

(ADVANCE) FOR RELEASE FRIDAY, DECEMBER 15, 1967

(ADVANCE) STANFORD--Biochemists at Stanford University School of Medicine have succeeded for the first time in manufacturing a synthetic DNA which displays the full biological activity of the natural molecule in living organisms.

The team, which may have come closest yet to creating life in the laboratory, includes Dr. Mehran Goulian, formerly a postdoctoral fellow at Stanford and now on the faculty of the University of Chicago, and Dr. Arthur Kornberg, professor and executive head of the Department of Biochemistry at Stanford. A third important contributor to the study is Cal Tech scientist Dr. Robert L. Sinsheimer who tested the synthetic material and confirmed its virulence.

Drs. Goulian and Kornberg have synthesized a fully infectious DNA virus, representing 5 to 6 genes. The test-tube product, when taken up by its bacterial host, orders the production of exact replicas of itself and the synthesis of all the components of the complete infectious virus.

The scientists reported their results in the December issue of the Proceedings of the National Academy of Sciences. Their work, culminating nearly eleven years of studies of DNA synthesis in the test tube, was made possible by grants from the National Institutes of Health and the National Science Foundation.

It was in 1959 that Dr. Kornberg won the Nobel Prize by turning a mixture of inert chemicals in a test tube into man-made DNA (deoxyribonucleic acid), the material that controls heredity. This early synthetic DNA possessed the physical and chemical properties of DNA found in nature, but it was biologically inactive.

Since then several research groups have reported attempts to synthesize an active form of the substance but the results have been equivocal. One explanation for this lack of activity was found in the enzyme DNA polymerase, which is used to promote formation of DNA. It contained enzymes, called nucleases, which produced breaks in the DNA. The smallest traces of these other enzymes in the DNA polymerase destroyed biological activity. Work by Dr. Kornberg and his associates has led to further purification of polymerase and the elimination of these nucleases.

-MORE-

This is an over-simplified account of the pioneer research that led to the synthesis of viral DNA. Drs. Goulian and Kornberg prepared a test-tube copy of DNA from a fully active DNA virus. Then using a variety of specialized laboratory techniques, they separated the synthetic material from the original DNA and used the synthetic DNA as a template or mold for a second round of replication.

They found it produced a fully synthetic DNA virus resembling the original in every detail. The process could be repeated many times with the new synthetic material, indicating no mistakes were made in the test-tube synthesis, according to the researchers.

In an interview today, Dr. Kornberg said the research represents an important step forward in understanding how viruses are duplicated when they enter cells and how DNA polymerase or similar enzymes make new DNA.

"If we know how to use this enzyme to copy this particular virus then we can copy other viruses," Dr. Kornberg said. "And we can copy them in ways in which we can modify their structure by putting in alternative or fraudulent building blocks to create new forms of the virus. We can then use the synthetic virus to infect cells and produce altered responses."

One possible future application is controlling certain forms of cancer, according to Dr. Kornberg. For example, DNA found in polyoma virus produces a variety of cancers in many animals. "I think it is reasonable to expect that the polyoma viral DNA will be synthesized by an enzyme system. With such a synthetic system we should be on our way toward figuring out what genes in the virus are responsible for the cancer response," he said.

Another possibility in the far-distant future might be the careful manipulation of laboratory synthesis of DNA as a means of modifying genes in a directed way.

DNA consists mainly of four building blocks which biochemists refer to as the genetic alphabet: A, T, G, and C. DNA has two major functions. It specifies in the many thousands of genes that make up an animal chromosome the complete chemical detail of the many thousands of enzymes required for the machinery and fabric of the cell. A gene is a stretch of DNA which contains about 1,000 building blocks. When this genetic alphabet is formed into a sentence, just as in any other language, the sequence spells out the recipe for a given genetic trait. The second function of DNA is to serve as a template or mold for the production of an exact copy of itself so that the cell may endow an offspring with identical information.

The Stanford research produced a fully active synthetic virus containing at least 5 to 6 genes, with a total of 5,000 to 6,000 letters. "I think the action of the enzyme in the test tube is impressive if you consider that a single copying mistake in the entire sequence would result in a garbled message and, therefore, in biologically inactive DNA," Dr. Kornberg said.

BIOGRAPHICAL INFORMATION

MEHRAN GOULIAN, M.D.

Dr. Mehran Goulian joined the faculty of The University of Chicago September 1, 1967, as an Associate Professor of Medicine and a Research Associate in Biochemistry.

A native of Weehawken, New Jersey, he received an A.B. degree in 1950 from Columbia University and an M.D. degree in 1954 from Columbia College of Physicians and Surgeons. He served his internship at Barnes Hospital in St. Louis, Missouri, and residency in internal medicine at Massachusetts General Hospital in Boston.

Dr. Goulian was a clinical associate at the National Cancer Institute of the U.S. Public Health Service from 1955 to 1957 and did additional volunteer medical work in African mission hospitals in 1957-58.

He is a member of Phi Beta Kappa and Alpha Omega Alpha honorary societies and is a diplomate of the American Board of Internal Medicine.

He was a fellow in medicine (hematology) at Yale University in 1959-60, then was at Harvard University from 1962-1965 as a research fellow in medicine and later as an instructor in medicine.

He was at Stanford University as a postdoctoral fellow in biochemistry from 1965 until September, when he came to Chicago.

Dr. Goulian's major fields of interest are hematology and DNA synthesis. He currently is doing independent research in the latter.

He and his wife, the former Susan Hook of New York, are the parents of two sons. They live at 5301 South University Avenue, Chicago.

Science Writers: Following is additional background for the story on first synthesis of biologically active viral DNA by Dr. Kornberg and his associates at Stanford University. It relates to the virus Phi X174 first discovered by Caltech biophysicist Robert L. Sinsheimer, one of the collaborators in the study.

ABOUT THE VIRUS PHI X174

Each DNA molecule, life's basic hereditary material, is usually described as a long, double strand of atoms. The strands are intertwined. It is believed that when a cell divides, the two DNA strands pull apart, each serving as a template upon which a complementary strand is assembled.

Scientists have been seeking in the chemistry of these pairs of strands the answers of how heredity works.

In 1959, Dr. Robert L. Sinsheimer of Caltech found that the DNA of the dwarf virus, named Phi X174, does not consist of two strands, but only one. Thus the little virus might be described as a simpler form of life. It consists of a single strand of DNA wrapped n a skin of protein. Dr. Arthur Kornberg and his associates have used the DNA of this virus as a template to produce a synthetic copy.

Phi X's mission in life is to infect and destroy bacteria which inhabit the human intestinal tract and also abounds in sewage. The virus is only about one-hundred-thousandth as large as its bacterial host. And its DNA content is only one-twentieth to one-seventieth that of other viruses which attack these bacteria.

It appears that Phi X's DNA chain is built on much the same pattern as the usual double-stranded chains. That is, the strand consists of "beads" of nucleotides. There are only four different kinds of these nucleotides. It is the sequence with which they are strung together that determines what hereditary characteristics they will impart.

Dr. Sinsheimer found that soon after the single-stranded DNA of the virus entered the cell it was copied to produce a double-stranded structure and some twenty minutes after invading the cell, the virus had directed the cell to manufacture about several hundred of the Phi X viruses, each capable of infecting a new cell.

BIOGRAPHICAL INFORMATION

ARTHUR KORNBERG, M.D.

With neither dismay nor bravado, Dr. Arthur Kornberg compares his research in DNA (deoxyribonucleic acid) with "spilling all the letters in an encyclopedia out on a table and then re-forming them into an ordered array."

The quiet, gently smiling professor and head of the Department of Biochemistry at Stanford University School of Medicine, won in 1959 a Nobel Prize by turning a mixture of inert chemicals in a test tube into DNA. To queries about producing life in a test tube, however, he has a Socratic sort of answer: "If you'd first care to define life."

The man trying to delve into the mysteries of nucleic acids, the core of living matter and the enzyme systems which maintain life, was born in Brooklyn in 1918. As a medical student at the University of Rochester, he turned a bout with hepatitis into his first published paper, "The Occurrence of Jaundice in Otherwise Normal Medical Students." After internship, he joined the National Institute of Arthritis and Metabolic Diseases, becoming chief of the enzyme and metabolism section in 1947. The reason for his concentration on basic biochemical research is an elegantly simple explanation of what makes a good scientist tick: "I just got tired of seeing something go in one end of an animal and come out the other without knowing what went on in between."

His research took him to Washington University in St. Louis, where he headed the Department of Microbiology during 1953-59. There he did the work that brought him the Nobel Prize, but Stanford University reaped the reflected glory, since Dr. Kornberg had just become executive head of the Department of Biochemistry at Stanford.

Since doing the original experiments, Dr. Kornberg and his associates have learned how to make many different types of DNA using different templates, including DNA from several bacteria, from various viruses, from the thymus gland of the calf and from the salmon sperm. This DNA, however, was biologically inactive. On December 15, 1967, after 11 years of intensive work, Dr. Kornberg and his associates reported in the Proceedings of the National Academy of Sciences that they had synthesized for the first time a totally synthetic copy of fully infectious viral DNA. This accomplishment has brought the obvious dream--the manipulation of nucleotides to produce tailor-made DNA as a means of controlling cancer and virus diseases--closer to reality.

Dr. Kornberg is a member of the National Academy of Sciences and a consultant to many private and public medical research programs in the United States and abroad. He is also the recipient of a number of honors and awards.

Dr. and Mrs. Kornberg and their three children live in Portola Valley on the San Francisco Peninsula. Mrs. Kornberg is also a biochemist with close appreciation of her husband's work.

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310

(ADVANCE) FOR RELEASE Thursday, DECEMBER 14, 1967

(ADVANCE) STANFORD--Scientists have found a synthetic plastic which powerfully stimulates production of human interferon, a natural antiviral substance that holds promise as an approach to control of a wide range of virus infections.

Work by Dr. Thomas C. Merigan at the Stanford University School of Medicine and by Dr. William Regelson, formerly of Roswell Park Memorial Institute in Buffalo and now at the Medical College of Virginia, has shown that pyran copolymer, a plastic manufactured by Hercules Company of Wilmington, Delaware, is taken up by the body's reticulo-endothelial system, which is the source of native interferon.

Interferon is a protein which is normally produced by cells in the body to limit the spread of virus infection.

Drs. Merigan and Regelson have shown pyran to be active against a leukemia-producing virus in mice and to have a potent and prolonged antiviral effect against a polio-like virus in mice. A single injection had a protective effect for two months, they reported.

The two investigators also confirmed that pyran had induced interferon in cancer patients participating in a cooperative study conducted by several hospitals on the East Coast. In this study, sponsored by the U.S. Public Health Service, other researchers are testing the polyanion pyran as a possible anticancer agent, independently of its interferon-inducing qualities. Drs. Merigan and Regelson have examined the serum of these patients and found pyran-induced interferon in levels similar to those obtained from patients with known virus infections.

"The studies demonstrate the ability of man to respond to nonviral agents like pyran with circulating interferon," Dr. Merigan stated in an editorial in the December issue of the American Journal of Medicine, and in a detailed report co-authored with Dr. Regelson in the December 14 issue of the New England Journal of Medicine.

"We stand on the threshold of an era that may see chemotherapeutic and other non-immunologic methods for control of virus infections in humans become as commonplace as the use of antibiotics against bacterial infections," Dr. Merigan predicted.

Ever since its discovery by Drs. Alick Isaacs and Jean Lindemann at the National Institute of Medical Research in London in 1957, interferon has been considered to have potential value in the control of virus disease in man, ranging from the most deadly virus infections to the common cold, for which no vaccines or chemical weapons are presently available.

Researchers had hoped that relatively harmless viruses could purposefully be introduced in patients to stimulate interferon production, or else that interferon might be purified from animal tissues for clinical use. -MORE-

Unfortunately hopes for its wide use were dashed by the finding that interferon from one species will not work except in cells of the same or closely related species. No practical way for purifying human interferon in clinically useful quantities is presently available and it is difficult to synthesize it because of its large size (molecular weight 30,000 compared to 6,000 for insulin).

Researchers, therefore, have turned their attention to agents that might behave like viruses in inducing treated cells to synthesize their own interferon. Last summer a research team from Merck Institute for Therapeutic Research reported that certain types of RNA (ribonucleic acid) were efficient interferon inducers in animals. Pyran and RNA are roughly similar in certain features of molecular structure.

At present pyran has certain drawbacks because it is not easily broken down by the body and accumulates in body tissues at certain dosages. Another of its side-effects is high fever. It is, therefore, not appropriate for widespread clinical use.

But Drs. Merigan and Regelson are hopeful their discovery will lead to joint efforts by interferon workers and polymer chemists to devise forms of the material which are more rapidly eliminated by the body and thus more suitable for use in man.

END ADVANCE FOR RELEASE Thursday, DECEMBER 14, 1967

Mailed December 5, 1967

Heart transplant / First Stanford Univ.

FILE COPY

A Stanford University medical school team led by Dr. Norman E. Shumway, Professor of Surgery, performed its first human heart transplant tonight.

The recipient was a 54-year-old steelworker whose cardiac disability caused him to retire eighteen months ago. His disease, chronic viral myocarditis, was far advanced. The patient had severe and irreversible heart disease.

The donor was a 43-year-old housewife who had suffered a massive brain hemorrhage. She had been in coma for almost 24 hours and had been supported with artificial respiration.

Dr. Shumway described the patient's postoperative condition as satisfactory but pointed out that he will be considered critical for the next several weeks. "This is only the first step," he said. "Now the real work and concern begin."

The operation was performed one month after Dr. Shumway had stated in an interview at the JAMA that his experimental work with animals during the last 7 years had shown transplantation of the heart to be feasible and that he and the Stanford team were ready for a human trial.

The operation began at 5 p.m. and lasted approximately four and a half hours.

A news conference with further details will be held at 1 p.m. Sunday in Room M106 in the Medical School.

FILE COPY

NEWS BUREAU
STANFORD MEDICAL CENTER

About a week ago, Virginia and Bill White were talking with friends about heart transplant operations.

"How marvelous," she said, "to be able to give someone else a chance to live."

Last Thursday night, Jan. 4, she and Bill celebrated their 22nd wedding anniversary. They were high school sweethearts.

The next night, at 6 p.m., Virginia White, 43, who never had had a serious illness, suffered a massive brain hemorrhage. In less than 24 hours, she was dead.

Shortly thereafter, a team of Stanford Medical School surgeons began the heart transplant operation.

"Knowing that she is helping another is easing our grief," said Bill White, who gave permission for the transplant. "She was the type who would want to do this. I've got two of the proudest children you ever knew. They think it's great."

White lives at 723 Valley Road, Santa Clara, with their children, Judy, 18, and Rickey, 12.

Judy, a freshman at West Valley Junior College, plans to be a dental hygienist, but is thinking strongly of Vista, the Federal Government's domestic Peace Corps. Rickey attends Curtis Junior High School.

White needed less than 30 minutes to reach a decision to give permission for the transplantation of his wife's heart.

"When I look back on it," said White, "I guess it really began Nov. 3, when I lost a dear friend to cancer. His wife urged that any contributions be given in his memory to the Stanford Medical School, and that seemed to me to be a magnificent thought.

"After my wife was hospitalized, our family doctor and the neurosurgeon told us there was no hope. I asked them if there was any type of research going on relating to what had happened to her, something where she could help.

--MORE--

"They said they didn't know.

"But a few hours later, Dr. Shumway, whom I've never met, phoned me and explained the possibility of a heart transplant. I asked for time to talk it over with the children and my wife's mother. They all said yes, and when I talked with Dr. Shumway about 30 minutes later, I said yes."

Mrs. White was an avid camper and an expert water skier, as are her husband and two children. The Whites helped form a bow-and-arrow club in the Santa Clara Valley, and she devoted her spare time at home to mosaics and flower arrangements.

With all this, she worked full time for the past six years with Philco-Ford on Fabian Way, Palo Alto, most recently as a junior programmer with the firm's space re-entry group.

The Whites, both born in Des Moines, met in 1940 in East High School, in a salesmanship and merchandising class. Both graduated in 1942, and were married four years later.

Her brother a pressman for Meredith Publishing Co., lives at 2248 SW First St., Des Moines. Her mother, Mrs. Nell Grubb, who now lives near the Whites, worked for 35 years in Meredith's bindery.

Mrs. White worked for a while after high school as a key punch operator for the Iowa Liquor Commission in Des Moines.

The Whites have lived in California for more than 20 years, the last 15 in Santa Clara County.

"We haven't done anything," said White. "She has. All we've tried to do is say it for her."

"Go ahead, don't waste any time. I want you alive and with me," Mrs. Ferne Kasperak said to her husband when he told her he was ready to consent to a heart transplant operation at the Stanford Medical Center.

Because of his condition, doctors had asked Mike Kasperak if he would consent to the operation--an operation which is technically feasible but involves high risk to any patient because of the natural tendency of the body to reject foreign tissue.

Mr. and Mrs. Kasperak were told of the uniqueness and the danger of the operation, but they were also told that the 54-year-old steelworker would not live much longer without it. He had suffered from a chronic heart infection, a condition which had turned his heart muscle into fibrous tissue and had weakened its pumping capacity.

Kasperak, according to his wife, agreed without hesitation. The donor was Mrs. Virginia Mae White, a 43-year-old Santa Clara housewife who had suffered a massive brain hemorrhage. She had been in a coma at the hospital for almost 24 hours and had been supported with artificial respiration.

Kasperak was forced to retire by his heart condition 18 month ago and move to East Palo Alto. He was an employee of the Laughlin Steel Corp., Cleveland, Ohio, for 30 years.

Mrs. Kasperak, a switchboard operator now on leave from Ampex Corp. at Redwood City, describes her husband as a "quiet, easy-going, lovable man with a lot of confidence in himself."

The Kasperaks have no children of their own. Mrs. Kasperak has a son in Cleveland, Harvey S. Glasener, 25, by a former marriage.

Kasperak was born in Lorain, Ohio. During World War II he served as an ambulance driver in Africa and in Italy.

He was referred to Dr. Donald L. Harrison, assistant professor of medicine and chief of Stanford's Division of Cardiology by his family physician, Dr. Martin Robinson of the San Jose Medical Clinic. Dr. Robinson, a former fellow in cardiology at Stanford, was present during the actual heart transfer from donor to recipient.

Stanford University
Medical Center News Bureau

Friday, January 12, 1968 10:30 a.m

Mr. Mike Kasperak's condition remains unchanged since yesterday. He is still on the critical list. His blood pressure, pulse, and temperature are normal, but the patient continues to have liver and kidney function abnormalities. His physicians report that dialysis may be reinstituted in spite of apparently adequate urine volume, and are concerned about his lack of progress with respect to the liver and kidney functions.

The patient continues to be fed intravenously and to be assisted in his breathing by artificial respiration part of the time.

Last night, with the help of nurses, Mr. Kasperak sat on a chair for 15 minutes during Mrs. Kasperak's visit in the intensive care unit.

The next progress report will be issued at 10 a.m tomorrow morning unless there is a major change in the patient's condition.

FILE COPY

Stanford University
Medical Center News Bureau

Saturday January 13, 1968 11:00 a.m.

Despite his excellent heart condition, Mike Kasperak, the nation's first adult heart transplant patient, has suffered what his physicians termed a "serious setback" this morning because of poor liver function. He is on the critical list.

Kasperak is presently described as "semi-comatose," attributed by his physicians to excessive accumulation of bilirubin in his blood. Bilirubin is a product of hemoglobin, the oxygen-carrying protein in the blood. Bilirubin must be removed from the blood by the liver. When the liver is functioning poorly bilrrubin builds up in the blood. Physicians believe this condition may be ~~is~~ aggravating the semi-cometose condition of the patient.

The physicians said that a large blood exchange transfusion will be done later in the day. They explained there is no bleeding and that the special transfusion is being done particularly to remove impurities in the patient's blood.

Kasperak's blood pressure and cardiac function are normal.

Peritoneal dialysis was re-instituted late yesterday to assist his kidney in spite of apparently adequate urine volume. (Peritoneal dialysis consists of injecting fluid into the peritoneum, the thin membrane lining the walls of the abdominal cavity. Impurities in the blood pass through the membrane and are then carried away.)

The patient continues to be fed intravenously and to be assisted in his breathing by artificial respiration part of the time.

The next progress report will be issued at 10 a.m. Sunday, unless there is a major change in the patient's condition. ~~Information throughout the day may be obtained through the Palo Alto Stanford Hospital's Nursing Service, 321-1200, Ext. 5181.~~

Mike Kasperak, America's first adult heart transplant patient, underwent a three-hour blood exchange transfusion today. But he remains on the critical list in semi-conscious condition at the Stanford Medical Center.

The transfusion was done primarily to remove impurities in his blood. Doctors used 10 units of blood. Earlier in the day, his physicians reported Kasperak had suffered a serious setback because of poor liver function.

His heart, transplanted last Saturday, is reported in excellent condition, with normal blood pressure and cardiac function.

Bulletin #14
Medical Center News Bureau
Stanford University School of Medicine

January 14, 1968 10:00 a.m.

In a medical bulletin issued this morning, doctors say Mike Kasperak's condition remains unchanged. His heart remains in good condition but he is semi-conscious.

During the night an enlargement of his gall bladder was noted, which was drained of fluid. (The gall bladder is a pear-shaped sac sitting under the liver just to the right of the stomach. Its job is to store and concentrate bile, an alkaline liquid manufactured in the liver. The gall bladder releases bile into the intestine where it helps to digest fats in foods and to neutralize acids that come from the stomach.)

Doctors suspect that an aggregation of blood and bile is blocking the duct or tube carrying bile from the liver into the small intestine and the gall bladder. For this reason, Kasperak will undergo drainage of the common duct at 10:30 this morning. The operation usually lasts 40 minutes. Doctors say this condition is correctable.

Kasperak yesterday received a large blood exchange transfusion to remove impurities in his blood and a slight improvement of his jaundiced condition was noted.

His heart is reported in excellent condition, with normal blood pressure and cardiac function this morning.

The next progress report will be made at 12 noon today.

Bulletin #16

Medical Center News Bureau

Stanford University School of Medicine

January 15, 1968 10:30 a.m.

In a report issued this morning, doctors said Mike Kasperak's crisis with his liver may be over. They said the patient has moderately improved since Sunday following removal of his gall bladder and drainage of the duct which carries bile away from the liver into the intestine. Doctors emphasized, however, that Kasperak's condition remains critical and that problems of rejection of his transplanted heart still lie ahead.

Doctors said Kasperak still suffers from short periods of semi-consciousness but this state also appears to be slowly improving.

His liver function is also returning ~~xxxxx~~ slowly to normal. Dialysis, a method of aiding the kidney, is being continued although his kidney function is much improved.

Kasperak's heart function continues to be satisfactory.

Stanford University surgeons tonight said the kidney transplanted to Mrs. Annabel Mann, 51, of Reno, Nevada, was not accepted by her body and was removed.

The half-hour operation was completed at the Palo Alto-Stanford Hospital at 8 p.m. The patient is being treated in the intensive care unit and is in satisfactory condition. She will be on peritoneal dialysis until a new donor is found and the patient recovers from the present operation, the surgeons said.

Peritoneal dialysis is a substitute method for kidney function. It consists of injecting a fluid solution into the peritoneum, the thin membrane lining the walls of the abdominal cavity. Impurities in the blood pass through the membrane and are then carried away.

The surgeons said general experience with kidney transplants has shown that failure of the recipient to accept a graft does not compromise the patient's ability to accept a graft from another donor later on.

Mrs. Mann had received a new kidney from the body of Mrs. Virginia Mae White, of Santa Clara, Saturday, who also was the donor for Mike Kasperak's heart transplant.

Meanwhile, Kasperak , the first adult heart transplant patient in the United States, continues to make progress although he is still on the critical list.

For the second straight day, Kasperak sat up on the side of his bed, dangling his legs over the side to maintain circulation. He was visited by his wife, Ferne, and wrote, "I love you," to her. A tracheotomy prevents him from talking.

His blood pressure is normal and his liver function shows some improvement, the physicians reported. I

STANFORD--Dr. Christian Barnard, South Africa's heart transplant surgeon, was among 400 cardiologists who attended an afternoon clinic at Stanford Medical Center Wednesday. The clinic was conducted by members of the faculty of Stanford's Division of Cardiology:

Dr. Barnard toured the facilities of the medical center, the laboratories of the Division of Cardiovascular Surgery, and met briefly with Dr. Norman E. Shumway, professor of surgery. The meeting between the two surgeons took place in the operating room where Dr. Shumway was performing an operation on a 20-year-old patient with a congenital atrial septal defect (a hole in the septum--the dividing wall between the two chambers of the heart).

The meeting was private. Dr. Harrison said the conversations with Dr. Barnard were extensive enough to provide us with information from his experience with heart transplants that will be of value to later cases that may be done at Stanford.

STANFORD--A rare chronic lung disease in humans has been linked to California's giant redwood trees (Sequoia sempervirens) by researchers at Stanford University School of Medicine and Palo Alto Veterans Administration Hospital.

The disease has an appropriate name--sequoiosis.

The cause of the lung condition has been traced to fungi in redwood sawdust. The condition was first identified in a 38-year-old sawmill worker with a four-year history of unexplained lung disease. The patient suffered shortness of breath, coughed intensely, and had lost 40 pounds. There was also an inflammation in both lungs. The patient had worked in the sawmill for 17 years.

Researchers believe the lung condition is caused by a reaction of the immune system of certain individuals to the redwood dust or fungal particles. Wood dust has not been reported previously as a factor in lung disease. But some respiratory ailments encountered frequently among farm workers are known to be caused by breathing of organic dust. The most well-known of these is a farmer's lung disease, associated with moldy hay.

The Stanford researchers are Drs. Herbert I. Cohen, Thomas C. Merigan, Jon Kosek, and Frederick Eldridge. Their findings were reported recently in the American Journal of Medicine. The work was supported in part by the National Institutes of Health, National Institute of Allergy and Infectious Diseases.

Tests have shown that inhaled redwood sawdust found its way into the alveoli, the tiny air sacs in the lungs. There the minute needle-shaped or irregular sawdust particles provoked a tissue reaction identical to that which occurs in patients who have breathed dust from maple bark, moldy hay, mushrooms, and other known organic substances, the researchers said.

These dusts of vegetable origin, added the researchers, contain fungi and the lung disease is a result of an allergic reaction to the fungal particles.

Further studies showed the patient's serum contained more antibodies--germ fighting substances--against redwood fungus extracts than did the serum of similarly exposed workers or a hospital patient control group. The patient's antibodies were directed against two types of fungi in the redwood, the physicians said.

Studies also confirmed that the immunologic reactions, seen in the sawmill worker, did occur in laboratory animals that were exposed to redwood sawdust.

The physicians said the patient's condition improved when he was removed from the environment of the sawmill.

No such fungus or antigenic particles could be demonstrated in pine, fir or beech sawdusts or in the redwood bark in contrast to the wood itself. However, cedar, mahogany, and ash contained material almost identical to the redwood sawdust fungus, the physicians said.

SHANGHAI--Double honors have recently been awarded Dr. Jon Eisenson, professor of speech and hearing sciences at Stanford University School of Medicine and director of the Scottish Rite Institute for Childhood Aphasia in Palo Alto.

Dr. Eisenson has been a[illegible] international research committee on dyslexia and world illiteracy for the World Federation of Neurology. The first meeting of the committee will be held April 3-5 in Dallas, Texas.

He was also awarded Honors of the American Speech and Hearing Association convention recently in Chicago. The award was given in recognition of Dr. Eisenson's contributions in teaching and research, and particularly for his significant writing for the profession.

Dr. Eisenson, an internationally known authority on aphasia, assumed directorship of the Scottish Rite Institute of Childhood Aphasia when it was opened in 1962. He and staff members study and treat aphasic children who are unable to speak or learn to read and write as a result of brain damage.

The service function of the Institute, according to Dr. Eisenson, is supported by a continuing grant from the California Scottish Rite Foundation, headed by Henry Gluckson, in San Francisco. Research activities are funded by a grant from the National Institute of Neurological Diseases and Blindness.

The Institute is a unit of the speech and hearing science section at the medical school.

STANFORD--A movable cart for the treatment of patients suffering from shock has been developed at Stanford University School of Medicine.

The "shock cart," as it is known, was the brainchild of Dr. Donald C. Harrison, head of the Division of Cardiology at Stanford. He was assisted by Dr. Mark Perlroth, instructor in medicine, Dr. Robert DeBusk, postdoctoral fellow in cardiology, Harry Miller, cardiology laboratory coordinator, and Tom Metcalf, a third-year medical student.

"We've been interested in studying shock for many years," says Dr. Harrison. "Since there is not a major unit or ward for patients suffering from shock in the Stanford Medical Center, we decided to design a portable unit which we could move to the bedside of any room in the hospital."

The cart, which is specially equipped, "can provide enough information to intelligently treat the complex physiologic abnormalities of shock," he says.

"Shock was once thought to represent only low blood pressure. This doctors have been able to determine directly," according to Dr. Harrison. "Now we know that low blood pressure results in a decreased perfusion of blood containing oxygen and other vital substances to the organs. Until now this information on tissue perfusion was only indirectly available."

Acute heart attacks are the primary cause of shock in patients.

"On a national level, 500,000 Americans suffer heart attacks each year, with 20 per cent of this total going into shock," Dr. Harrison notes.

"While patients suffering from other heart ailments have been helped considerably by new drugs and electronic heart monitors, the outlook for the patient in shock following a heart attack is not good. There is an 80 per cent mortality rate among these patients whose hearts fail to beat strongly enough to keep them alive and on whom attempts to strengthen the heart with drugs often fail," he says.

Another cause of shock is bacterial infection in the blood stream. This condition is usually associated with other diseases such as cancer or certain types of treatments such as massive irradiation or use of drugs to treat cancer or immunologic disorders.

Equipment on the shock cart includes transducer systems for measuring blood flow and blood pressure in several locations of the body. The transducers convert the measurements into an electrical signal which can be amplified and recorded.

-MORE-

A retractable arm on the top of the cart is designed to hold three transducers. "These can be placed beside the patient's arm or near his heart--wherever we want to record the pressures after the specific catheters and tubes have been placed into the blood vessels of the patient," Dr. Harrison points out.

Another feature of the mobile unit is the facility for recording electrocardiograms (EKG).

"Once it's in use, there is a rapid developing mechanism for processing the pressure and EKG recordings so that they are instantaneously available for study," he says.

A digital clock on the cart accurately times the data on the shock patient as it is collected and recorded.

"Once we have obtained and analyzed all the extra information made available to us by the shock cart, we can develop a physiologic plan for managing the patient," Dr. Harrison says.

"We would like to increase our study of shock and are gradually seeing additional patients as doctors recognize the importance of the essential information which the shock cart can provide," Dr. Harrison points out. "In fact, we foresee the time in the near future when everyone having a patient of this type will want to have these kinds of studies done."

At present, one shock cart is in use at the Stanford Medical Center. This prototype model was built by Honeywell, Incorporated which will produce the cart commercially. Dr. Harrison and his associates worked six months with representatives and engineers of Honeywell on its design and construction.

An additional cart is being used in the cardiology unit of the Veterans Administration Hospital in Palo Alto and the University of California Medical Center has placed an order for the new shock cart.

Dr. Harrison expects that the mobile cart will be widely used for studying patients with shock in a number of other hospitals in this area and perhaps in other areas of the country.

(ADVANCE) FOR P.M. RELEASE MONDAY, FEBRUARY 19, 1968

STANFORD--Surgeons at the Stanford University School of Medicine have replaced defective aortic heart valves in 40 patients with transplants from human donors who have died.

Thirty-five patients have received the new valves successfully. There were five postoperative deaths, none of which was related to valve dysfunction. Of the 40 patients, 28 were men and 12 women. All patients were severely limited by their valve disease and four of them were near death prior to the valve replacement operation. The patients are leading normal lives.

Drs. Edward B. Stinson, William W. Angell, Albert B. Iben, and Norman E. Shumway reported their results with the graft technique today at the Pacific Coast Surgical Association meeting in Honolulu.

For some time researchers have been seeking a way to use human heart valves in replacement surgery instead of plastic ones. Surgeons have known that if a heart valve is removed from a donor soon after death, and transplanted into a patient within five days, it will function effectively. The same technique has been used widely in England, New Zealand, the Mayo Clinic, the Medical College of Virginia, and the University of Washington.

"We believe," the surgeons said, "that the experience reported here and other published reports justify the current enthusiasm over the use of aortic valve homografts. That these valves may function satisfactorily over long periods of time, up to eight years...has been proven." (The aortic valve controls the flow of blood from the heart into the body's main artery).

The main advantages of the graft technique is that patients are not required to take anticoagulant drugs to prevent clotting and the danger of late infection is minimized, the surgeons reported.

The surgeons said "no instance of deterioration of the implanted valves has appeared in up to 10 months of observation" in their patients and immune rejection of the transplanted valves has not been a problem.

STANFORD--Because of concern for the welfare of their patients, pediatricians at the Stanford University School of Medicine have not and will not report cases of LSD and other hallucinatory drugs to the police.

A statement, issued today by the full-time faculty of the Department of Pediatrics, noted that use of these drugs can have adverse medical consequences. The physicians emphasized their principal concern is the medical problem--not its legal ramifications.

The pediatricians' statement was prompted by a recent alleged case of two preschool-age boys in San Mateo County who were accidentally given LSD and the subsequent trial of their father. An erroneous report attributed the evidence given to the police to staff members of the Palo Alto-Stanford Hospital Center.

"The case has highlighted a medical problem of growing concern," the pediatricians said. "It is fervently hoped that these comments will encourage those faced with acute problems of this type to seek whatever professional help may be necessary free from fear that their requests to help will be more baneful than beneficial."

"From a legal point of view," the pediatricians said, "it is true that LSD is included in the list of 'dangerous drugs.' Its possession or use is a misdemeanor under the laws of the state. These comments in no way imply any judgment on the justice or desirability of the law.

"However, it should also be emphasized that according to legal experts physicians are under no obligation to report violations of this or any other drug law which may come to their attention in the course of their practices. Such action or lack of it is entirely up to the discretion of the individual doctor.

"It is our strong conviction the great majority of physicians take the view that the welfare of their patients demands assurance to the patients that their doctors' sole concern will be with the medical problem."

-MORE-

The author of the statement, Dr. Norman Sissman, associate professor of pediatrics, wrote that contrary to press reports, the Palo Alto-Stanford Hospital Center did not report the San Mateo incident to the police. "No employee of the hospital or member of the faculty of the Stanford University School of Medicine initiated any contact with the police."

"More important than this inaccuracy," Dr. Sissman added,"is the fear which the incident appears to have engendered in the minds of many Bay Area citizens as to the consequences of seeking medical help for the treatment of adverse reactions following the ingestion of drugs with 'mind-altering' properties.

"Many people have concluded that calling a physician under such circumstances can result in notoriety, legal prosecution, and even imprisonment. Pediatricians at the Medical Center feel strongly that this is an unfounded fear and are concerned about the possible results of such an attitude."

The pediatricians warned that since drugs can now be obtained only illegally, there is no assurance the dosage of any pill, capsule or fluid preparation corresponds to what it was claimed to be, nor is there any reliable way to determine if additional chemical compounds have been added. Furthermore, observations have shown reactions produced by known amounts of these drugs depend to a large extent not only on the background and personality of the user, but also on the circumstances under which the drug was taken. Thus ingestion of psychedelic drugs may result in an adverse reaction or a "bad trip," characterized by symptoms such as anxiety or panic, and possible profound psychological changes.

"In recent years, medical institutions and physicians have successfully treated such problems," the Stanford pediatricians commented. "Their primary and sole concern has been the well-being of those who come to them. That such confidence and rapport should be placed in jeopardy by misinformation surrounding this isolated case is medically deplorable and potentially dangerous to many people."

STANFORD--Dr. John A. Luetscher, Jr., professor of medicine and head of the division of metabolic diseases and endocrinology at Stanford University School of Medicine, has been presented the Mayo H. Soley Award of the Western Society for Clinical Research.

The award, which was established shortly after the death of Dr. Soley in 1949, is presented for "outstanding research work to a worthy investigator of the West." Dr. Luetscher is the first recipient of the honor which was presented at the Society's annual meeting in Carmel Feb. 2.

Dr. Soley was an active investigator at the University of California Medical School where he was professor of medicine and assistant dean. He was instrumental in the founding of the Western Society for Clinical Research and served as its second president.

Dr. Luetscher, who has been an active member of the Society for 18 years, was cited for his "truly great research accomplishments which have had impact throughout the medical world."

Dr. Luetscher is noted for his research of the causes of edematous states. Commonly known as dropsy, edema is an excessive accumulation of fluid in the tissues. While seeking the causes of dropsy, Dr. Luetscher was first to show that a hormonal factor, later called aldosterone, was involved in various edematous conditions. He has also contributed greatly to the knowledge of salt and water metabolism in the production of edema.

In 1963, Dr. Luetscher received the John Phillips Memorial Award from the American College of Physicians for his outstanding metabolic research.

Dr. Luetscher received his M.D. degree in 1937 from Johns Hopkins. He joined the Stanford faculty in 1948.

ADVANCE FOR P.M. RELEASE FRIDAY, MARCH 22, 1968

FILE COPY

WASHINGTON, D.C. -- A Stanford University cardiovascular surgeon told a Senate subcommittee today that he welcomes federal efforts at educating the public about health research and such areas as heart transplants.

But he emphasized that there is more at stake than heart transplants. Liver, kidney, pancreas, even bowel and lung grafts are and will be feasible. "We are on the threshold of a wondrous new era in medicine, and doctors will need help to realize fully its potential," Dr. Norman E. Shumway told the senate group.

He noted that, while artificial heart devices may someday be effective in adults, clinical trials of heart transplants are worth pursuing because only transplants appear to have any future in infants and children. The transplant alone would appear to offer hope for congenital heart disorders that cannot be treated by present methods, he said.

Dr. Shumway, professor of cardiovascular surgery at Stanford University School of Medicine, is the surgeon who transplanted the heart of a 43-year-old housewife into the body of a 54-year-old steelworker at Stanford Medical Center. The patient died of other complications 15 days after his initial surgery.

Dr. Shumway appeared before the Senate Subcommittee on Government Research to comment on a resolution proposed by Minnesota's U.S. Senator Walter Mondale. The resolution calls for the creation of a national commission on the ethical and social implications of health science research and development.

"I feel much can be done if such a commission investigates and educates," Dr. Shumway said. "Transplantation of the heart, fortunately or unfortunately, cannot be done without public notice and public support. Criteria are evolving with respect to donors and recipients which must be discussed in the light of the new technology."

One of the critical areas in which surgeons are asking lawmakers for help is a workable definition of death. The surgeons would prefer brain death to be that criterion.

It may seem revolutionary, said Dr. Shumway, to suggest that the physician is no longer bound by the heart beat as the primary criterion of life. Yet, every day in hospitals all over the world the heart is intentionally stopped to facilitate open heart surgery. No one would consider these patients dead.

He suggested that death be defined in terms of organs which cannot be transplanted. "Sensitivity of the brain to oxygen deprivation, the irreversible nature of important brain injury, and the idiosyncrasies of neuroanatomy certainly preclude brain transplantation at this moment," Dr. Shumway said.

Selection of the ideal recipient for a heart transplant is more of a problem than definition of the perfect donor, the surgeon said. Heart transplantation cannot be termed therapy, at least not yet, therefore the recipient must be one whose death appears imminent or whose life is so unbearable that he qualifies for this kind of clinical trial. (more)

The donor cannot be dead in the conventional or time-honored sense. He must be dead in the sense that the brain is irreversibly and completely destroyed. This condition can be clearly and unmistakably diagnosed.

Only acute donors have been utilized in transplants performed thus far, said Dr. Shumway, but the door is open for use of chronic donors, patients who know they are dying of diseases unrelated directly to the heart, who wish to donate their organs for transplantation.

Consent for organ usage may be granted by the chronic patient himself, Dr. Shumway said, but the fact the next of kin controls disposition of the body after death and may decide not to honor the request, can create difficulties. Here legal reform may be necessary.

Dr. Shumway developed the basic techniques used in heart transplants with Dr. Richard R. Lower of the Medical College of Virginia. Replying indirectly to critics that heart transplants are premature, Dr. Shumway said the three primary goals have been achieved in the laboratory. These are 1) a feasible surgical method, 2) physiological performance of the transplanted heart after separation from the central nervous system and, 3) control of the immune reaction.

Each development was published in medical and surgical journals. Financial support was provided by the National Institutes of Health and the American Heart Association for fellowship stipends as well as for research. While these discoveries were being made in the laboratory, transplantation of unpaired organs and cadaver kidneys was gaining clinical acceptance. The medical and social climate seemed appropriate for clinical application of heart transplantation.

Commenting on the problem of immune reaction, Dr. Shumway explained that early trials utilized drug treatment similar to that used in kidney grafts. Although rejection was held in check, no real prolongation of life was affected in animals.

The conclusion was inescapable that heart tansplants required special treatment, Dr. Shumway said. After considerable trial and error the concept of demand or intermittent therapy was evolved. Dogs were living up to one year when chemotherapy was administered in accordance with certain specific but easily identifiable indicators of rejection in the electrocardiogram.

STANFORD--Eighteen months ago, Paul Bissinger, Sr., prominent San Francisco businessman, was told he had cancer.

"My first thought was that I had an incurable disease," he recalls.

Today, following an intensive program of radiation therapy at Stanford University School of Medicine, Bissinger has returned to a full and normal life as husband, father of two sons and a daughter, and president of Bissinger & Co. He also serves on the board of directors of Wells Fargo Bank in San Francisco, United Air Lines, the San Francisco Symphony, and the World Affairs Council.

For Bissinger the trouble began with a small cyst behind his ear. "Although to me it seemed to be simply a matter of having the growth removed, my physician in San Francisco immediately foresaw the danger," he says. A biopsy showed the cyst to be malignant.

"I remember asking 'Is there any hope for treatment? Where?,'" Bissinger relates.

He was referred to the Division of Radiation Therapy at Stanford where doctors found cancer of the lymph node system, or lymphosarcoma. The lymphatic system, a network of small "glands" ranging from the size of a pinhead to that of an almond, is part of the infection-fighting mechanism of the body. It also acts as a partial filter system to stop the spread of malignancies throughout the body although the system itself is susceptible to cancer.

For six months, Bissinger received intensive treatment four times a week. The radiation therapy was conducted on a medical linear accelerator at Stanford which produces high-energy X rays for treatment of cancer.

To say that Bissinger is grateful for the treatment available at Stanford is an understatement. His feelings, plus those of other former patients of radiation therapy, whom Bissinger describes as "pretty darn healthy," go much deeper.

The former patients and interested associates, with Bissinger as spokesman, have launched a fund raising campaign. These "Friends of Radiology" hope to raise over $300,000 to expand the facilities of Stanford's Division of Radiation Therapy.

"People who have not been touched by cancer cannot imagine the despair of those afflicted with the disease. Nor can they experience the exhilaration I have felt in knowing I have been cured," Bissinger says.

"It is only because I spent hours, with scores of other patients in the busy, cramped quarters at Stanford that I realize how very fortunate I was to have been treated. If we are able to financially help with the expansion of facilities at Stanford, thus giving more cancer victims the chance we were given, perhaps our debt of gratitude will partially have been paid.

-MORE-

222 There is little doubt but that the present radiation therapy facilities are overtaxed. Over 1,300 new patients are treated each year, a dramatic increase from the 250 new patients seen in 1956 when the first accelerator was adapted for medical use in the fight against cancer by Dr. Henry S. Kaplan, professor and executive head at the Department of Radiology. This accelerator, designed and built by Stanford physicists, is still heavily used today. A second accelerator was installed in 1962.

Nearly 2,400 treatments for various types of cancer are given each month with existing equipment and personnel operating on a 10-hour basis each day. This figure marks a 300 per cent increase over the number of treatments given per month in 1960. The daily patient load averages 141 persons.

"Cancer is a whole spectrum of diseases, depending on its location and its aggressiveness in spreading," according to Dr. Malcolm A. Bagshaw, head of the Division of Radiation Therapy. "Radiation therapy can be used to treat certain types of cancer--Hodgkin's disease, cancer of the cervix, mouth, vocal cords, throat, skin, lip, eye and some brain cancers. Unfortunately, there are other types of the disease which are very difficult, and in many cases impossible, to treat with radiation--leukemia, cancer of the bone, stomach and lung."

Continuing research, supported by the government, promises new methods of fighting cancer with radiation therapy, but funds are badly needed to bring these advances from the research laboratory to the clinics for application in the treatment of patients. Paul Bissinger and the "Friends of Radiology" strongly feel that this is an area where the private sector business, can be of immeasurable assistance.

"We've simply reached a saturation level,"Dr. Bagshaw says. At present new patients must make an appointment three to four weeks in advance. Paul Bissinger remembers this waiting as "endless and demoralizing." Because of the lack of facilities, about 10 per cent of those desiring treatment must be turned away or sent elsewhere.

Expanded facilities would allow for the treatment of 25 to 30 per cent more patients.

"Our initial plans call for the installation of a third accelerator, plus replacement of the older model in use now,"according to Dr. Bagshaw. Support facilities such as additional examining and dressing rooms are also needed.

Equally important, if not more so, is the need for an increased staff of radiation therapists and technicians. "You can have all the machines in the world, but without highly trained personnel, very little is accomplished," Dr. Bagshaw stresses.

Stanford, because of the exceptional stature of the Department of Radiology, does not suffer from a shortage of doctors specializing in radiation therapy as does the rest of the country in general. At present there are only 50 radiation therapists being trained in the entire country. Nine of these are at Stanford.

Additional funds in the future could be used for such items as financial support for those who need radiation therapy but cannot afford it or providing education and recreational programs for those patients from other parts of the country who often spend months living in a motel while undergoing treatment.

There is little question as to the success of radiation therapy in the treatment of cancer. It can best be exemplified in the relaxed smile of Paul Bissinger and the sparkle in his eyes. Although he still appears at Stanford every two months for a checkup, there has been no recurrence of the cancer. ### Mailed March 19, 1968

STANFORD--Medicine and Modern Warfare is the topic of a series of discussions planned this spring under sponsorship of Physicians for Social Responsibility.

"Biological Warfare, National Defense and International Controls," will be the subject of the first lecture March 14 by Prof. Chauncey Leake, professor of pharmacology at the University of California School of Medicine.

Topics to be covered in April include "Preventive Medicine and Modern Warfare," April 2; "Chemical Warfare--The Agents," April 11; "Biological Warfare--The Agents," April 18.

Two discussions are scheduled for May--"Medical Ethics and Modern Warfare--The Issues," date undetermined; and "Civilians in Time of War--A Psychiatric Viewpoint," May 16.

All of the lectures will be held in Room M-110 of the Stanford Medical Center at 7:30 p.m. They are open to the public.

Physicians for Social Responsibility is an independent, national organization, headquartered in Boston. The local chapter has been formed this year with members from the medical profession throughout the Bay Area, including members of the faculty of Stanford University School of Medicine. The organization has no formal ties with the University.

When the national organization was formed in 1961, its initial concern was the medical consequences of nuclear warfare. This has since been expanded to include chemical and biological warfare also.

"The increasing evidence of the development and production of these weapons makes it urgent that the physician concern himself with their medical and moral implications to mankind," says Dr. K. D. Beernink, spokesman for the local group. Dr. Beernink is a postdoctoral fellow in microbiology at Stanford.

FOR P.M. RELEASE FRIDAY, MARCH 8, 1968

WASHINGTON, D.C.--A Nobel Prize-winning biochemist today suggested that human beings may soon look forward to correcting hereditary defects and to curing diseases by the introduction of new genes into their bodies.

The biochemist, Dr. Arthur Kornberg, of Stanford University School of Medicine, speculated further that it might be possible to use harmless viruses as vehicles for delivering genetic information into cells where it is needed.

Dr. Kornberg is the scientist who, with Dr. Mehran Goulian of the University of Chicago, and Dr. Robert Sinsheimer of Caltech, produced a completely artificial copy of the inner core of a virus (deoxyribonucleic acid) and demonstrated it to be as infectious as the original. Their research was reported in December in the Proceedings of the National Academy of Sciences.

Dr. Kornberg presented his views in testimony before the Senate Subcommittee on Government Research. The Senate group is holding hearings on a resolution proposed by Minnesota's U.S. Senator Walter Mondale. The resolution calls for the creation of a national "Commission on the Ethical and Social Implications of Health Science Research and Development."

Dr. Kornberg said he was in essential agreement with the opinions expressed by Stanford's Nobel Prize-winning geneticist, Dr. Joshua Lederberg, also testifying before the Senate subcommittee. Dr. Lederberg said he opposed formation of a national commission charged with making substantive prescriptions, after one year's study, about the biological policy of the human species. Rather a commission should be formed "to make recommendations on the best ways to educate the public and its political representatives on the impact of science, on how to reach informed decisions on biological policy consistent with our democratic ideals."

"The commission's report," Dr. Lederberg said, "might be the first step in the educational process by helping to air the most pressing questions and weigh their priority against other challenges. He observed that clear thinking and rational decision on biological change is hardly helped by invoking slogans like "genocide," "who decides on life and death," or "genetic tampering."

"What really startles and intrigues people is that genetics or heredity is simply chemistry," Dr. Kornberg told the committee. "It is a young and difficult branch of chemistry. After 20 years of work on DNA in laboratories throughout the world, we can begin to reconstruct some of the very simplest patterns of DNA duplication in the test tube. In the next 20 years this work must be made more precise, varied and extensive. Genetic engineering would then come more into prospect.

-MORE-

"What will genetic engineering bring? We can look forward to the correction of genetic defects, the cure of diseases due to defective or missing genes. At some future date, it should be possible to cure a patient with anemia due to defective hemoglobin. Current treatments consist only of blood transfusions and cannot cure disease."

Dr. Kornberg suggested that when the gene for human hemoglobin is identified, separated and reproduced in quantity in the test tube at some unspecified future date, it would be possible to include this gene in one of the many harmless viruses and use it as a vehicle for delivering genetic information into cells where it is needed.

Viruses are tiny biological agents that contain small bundles of genes. A virus particle attaches itself to a cell and, like a tiny hypodermic needle, squirts its genetic material through the cell wall. This mechanism could be used to counteract anemia.

"Our problem in this branch of science today, and for the foreseeable future, is not too much but too little knowledge," said Dr. Kornberg. "I see no ethical or moral problems that are different in kind or quantity that face us today with this new knowledge of genes and gene action. I do see the need for congressional action, to mobilize the talent and resources throughout the world to exploit the opportunities to expand our knowledge of the molecular mechanics of man.

"We have been and continue to be the objects of nature's genetic engineering. Often we are its victims."

Dr. Kornberg explained a single building block in any gene in the DNA is altered either by an agent such as X rays, by radioactive fallout or by an error in the cell's copying process. "The chances are 1,000 to 1 that any alteration in the gene will make the highly refined and evolved cell defective," Dr. Kornberg said. "In the case of human hemoglobin we have recognized over a dozen distinct blood disorders which are due to a single alteration in the gene which carries the message for hemoglobin."

Despite the promising leads and insights into gene structure, Dr. Kornberg had bitter words for the present state of knowledge of genetic chemistry which he termed "pitifully weak."

"Scandalously little support or encouragement is given to chemists who work in this area," he said. "We know that molecules determine what we are as men and how we behave. Yet we know less about the molecules of our chromosomes and our brain than we do about the molecules in Australian wool. This is because the Australian wool growers have for many years recognized the value of basic research in the composition and chemical properties of wool."

Dr. Kornberg urged the subcommittee to help "expand our research into the molecules, genes and cells of man. This is the soundest investment I know of to bring us closer to a deeper understanding of growth and aging, of our nervous system and behavior."

-MORE-

He pointed out that support for nucleic acid chemistry and other areas of basic research, never adequate, has in 1968 dropped below the critical point. "For the investigators who want to work in this field, this is discouraging and frustrating," he said. "For the medical practitioner who hopes one day to have the advantage of fundamental findings in his clinical practice, the implications are tragic."

Dr. Lederberg agreed with Dr. Kornberg. "The replication of DNA and the transplantation of the human heart have dramatized the advance in biological science," he said. "But they are only the most visible signposts of a deeper revolution. This is the understanding that human intelligence and industry, expressed in science, have brought the species to a new level of mastery. There is no enterprise consistent with the laws of physics and chemistry that is beyond human reach. But, of course, we reach nowhere without the concert of human will, without effective social decision on the priority of our commitments."

STANFORD--A two-fold program to develop both a new concept in the management of patients with leukemia and a joint interdisciplinary teaching program in the study of malignant diseases has been initiated at Stanford University School of Medicine.

The program will be funded by an initial grant of $24,890 from the Alexander and Margaret Stewart Trust of Washington, D.C. which was created under the will of Mary E. Stewart. Announcement of the grant was made today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine.

"Not only will the program allow for the rigorous, controlled treatment of leukemia patients, but it will serve as a model of cooperative practice between a segment of the Medical School faculty and the community," according to Dr. Glaser. "The interdisciplinary teaching program by the divisions of oncology, immunology, genetics and infectious diseases of the Department of Medicine will also provide a special learning experience for postdoctoral fellows, house officers, and students in training."

"The cohesion of this diversified group and the pooling of their ideas, knowledge, and skill could produce new ideas which might prove fruitful in the understanding and management of malignant diseases," Dr. Glaser said.

Although chemical treatment of leukemia in most cases has proven unsuccessful, it has been known for some time that certain forms of the disease are more amenable to therapy than others. Also, certain unusual aspects of the cancer have been identified which provide clues for future investigation. These include relationships to virus infections, to certain rheumatic diseases, and to diseases of the immune system such as cancer of the bone marrow.

The new program will pool the experience and effort of hematologists on the Medical School faculty with a group in the surrounding community. All leukemia patients and their treatment will be evaluated jointly.

Advantages to the cooperative approach are:

--The identification of patterns of leukemia in the community with more rigorous diagnosis than is usual;

--A pooling of experience in treatment so that uniform appraisal of drugs and their effectiveness will be possible;

--The opportunity to select from the total group of patients those with unusual manifestations who might benefit from evaluation by other groups within the Stanford Medical Center.

The patient management and joint teaching program will provide medical students and house officers with training in the care of patients while simultaneously engaged in investigative work in various subjects relevant to oncology.

STANFORD -- Dr. Carl V. Moore, Busch Professor and head of the Department of Medicine at Washington University in St. Louis, Mo., will deliver the third annual Lowell Rantz Memorial Lecture April 27 at Stanford University School of Medicine.

His talk, entitled "Iron Nutrition and Deficiencies--A World Wide Problem," is scheduled for 2:00 p.m. in Room M 106 of the medical school. It will highlight the eighth annual Stanford Medical Student Day, sponsored by the Stanford Medical Student Association with support from the Stanford Medical Alumni Association and a gift from the Palo Alto Medical Clinic.

Dr. Moore, former dean of Washington University School of Medicine, is a past president of the American Society of Hematology, the American Society for Clinical Investigation, and the Central Society for Clinical Research. In 1959 he received the Joseph Goldberger Award in Clinical Nutrition from the American Medical Association.

Dr. Moore received both his A.B. (1928) and M.D. (1932) degrees from Washington iversity . He has headed the Department of Medicine since 1955.

"The main purpose of Medical Student Day is to provide students with an opportunity to report on research projects and other accomplishments," according to Ronald Adler, fourth-year student and chairman of the day's events. "It also enhances communication between the medical students, faculty members, alumni, and local physicians.

Several student reports will be given from 1:15 to 2:00 p.m. and from 3:00 to 4:15 p.m. Abstracts of all papers will be included in the program. Other activities include presentation of awards by the alumni association, and a social gathering following the afternoon session.

The afternoon program is open to alumni, medical students, medical school faculty, Palo Alto physicians, nursing students, and personnel of the Palo Alto-Stanford Hospital Center.

EDITORS: The following story transmitted on Business Wire 4/19/68

STANFORD -- Terms of a proposed agreement on the future of the Palo Alto-Stanford Hospital were disclosed today by Stanford University and the City of Palo Alto.

The agreement will enable the University to own and operate the hospital for both community and medical school patients. The documents will require approval by both hospital owners.

Terms agreed upon by City and University negotiators were based on a proposal submitted to the City by University President Wallace Sterling last January. The chief negotiators were City Manager George Morgan and Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine.

Morgan said the suggested agreement "contains commitments for hospital services to the residents and physicians of the community in accordance with those put forth by President Sterling, and in some areas exceeding the original proposal.

"For the Palo Alto resident to be the beneficiary of these services free of a tax burden for a period of 40 years must be recognized as being of a very substantial value."

Dr. Glaser called the agreement "a very fair transaction that will strengthen the basic spirit of cooperation between the Medical School and the City, and will ensure continued high quality care for Palo Alto residents."

The main points of the agreement are the guarantees it provides to the City in meeting its objectives with respect to health care of its citizens. It also guarantees continued access to hospital facilities for all community physicians now on the staff.

Palo Alto-Stanford Hospital is owned jointly by the City and the University. Palo Alto has access to 220 beds in the main 420-bed hospital and 150 beds in the nearby Hoover Pavilion. The City also leases 32 acres of land from the University on which the facilities are located.

The City has expressed the desire "to get out of the hospital business." Stanford feels that a single ownership would enable its medical school to develop a true university hospital that is responsive to the emerging needs of medical education.

Under the terms of the agreement, Stanford will acquire Palo Alto's holdings and will operate the hospital, including the Hoover Pavilion. The University will grant staff privileges to all community physicians presently on the hospital staff for the remainder of their professional careers. A total of 370 beds now used by patients of community physicians will continue to be available to them. Palo Alto residents will be given admission priorities in non-emergency cases. In addition, community doctors will have access to new facilities that will be built by the Medical School.

-more-

The University has agreed to meet the payment schedule for the City's hospital construction bonds totalling $3.5 million in principal and interest over a 19-year period. In addition, Stanford would pay the City $500,000 in cash.

If Hoover Pavilion is closed because of the availability of 150 beds elsewhere in the community, provided by an agency other than Stanford, another $500,000 will be paid to the City.

The proposed agreement envisions a unified medical staff. Presently, the hospital has two medical staffs -- Palo Alto and Stanford -- each operating under its own rules and by-laws.

Dr. Daniel J. Feldman, associate professor and head of the Division of Rehabilitation Medicine at Stanford University School of Medicine, has been appointed professor and chairman of the Department of Rehabilitation Medicine at the Medical College of Ohio at Toledo.

He will join the faculty of the College September 1, 1968.

Dr. Feldman assumed responsibility for the rehabilitation division at Stanford in 1960, and since that time has developed a program which has been praised by authorities in his field. The division which receives more than 17,000 patient visits yearly has helped many residents in the community -- amputees, blind or permanently crippled -- to return to meaningful lives once more. He was also responsible for developing demonstration programs for treating the disabled in California's rural areas and aiding local physicians in bearing the responsibility for rehabilitation of such patients.

Dr. Feldman came to Stanford from the New York University School of Medicine, Institute of Physical Medicine and Rehabilitation. He is a graduate of Columbia University and New York School of Medicine. He is a member of numerous professional organizations and a consultant to the Palo Alto Veterans Administration Hospital, Crystal Springs Rehabilitation Center at San Mateo, and Stanford Children's Convalescent Hospital in Palo Alto.

STANFORD -- Major changes in curriculum to allow students to become physicians in the flexible atmosphere of a graduate school have been approved by the faculty of the Stanford University School of Medicine.

The changes are outlined in a document made public today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school. Proposed initially by the committee on medical education, the report calls for efforts "to provide students with greater opportunities for studying medicine in the context of their own needs, abilities, and ambitions than is now possible."

Specifically, the report recommends: 1) redefining the present "core" curriculum with increased elective opportunities for satisfying requirements in subject areas, 2) allowing students to develop highly individualized study plans and, 3) establishing an appropriate faculty body to implement the curriculum proposals by September, 1968.

The new plan, prepared by the committee under the chairmanship of Dr. LeRoy A. Pesch, associate dean, is considered likely to draw wide attention in medical circles, where Stanford's curriculum is already regarded as more flexible than most.

In 1959, the Stanford medical curriculum was completely rebuilt to improve the education of the future doctor by spreading his studies over five years instead of four, teaching him principles rather than mastery of specific detail, and emphasizing the essential unity of biology and basic medical sciences, and the interdependence of medicine with other fields.

One of the key elements of the initial Stanford Plan of Medical Education was the recognition that there has to be independence and flexibility in the scheme of medical education. These two ingredients were provided by the establishment of a "core" curriculum, which includes essential instruction for every medical student, with "free" time for electives.

However, after nearly eight years of experience, the faculty concluded that "the curriculum as now implemented did not completely achieve its objectives as a true graduate experience." The report considers the present plan too uniform to be suitable for the great variety of students who enter Stanford medical school.

For example, Dr. Glaser explained, the curriculum made no allowance for the fact that a student who majored in biology and another who studied liberal arts during his undergraduate years should be given substantially different courses of study in their professional school.

Despite the adoption of a rather unusual curriculum, the students' contact with patients was generally delayed until the third year and the beginning of the clinical studies. This, in Dr. Glaser's view, has perpetuated the isolation which some students feel from clinical medicine and has hampered the emergence of a clear inter-relationship between medical science and medical practice in the experience of the student.

-MORE-

Dr. Glaser stressed that a "core" curriculum to provide the essential common ground of information in the biological, behavioral, and clinical sciences would still be required of all future physicians. But the student will have elective options or different ways of meeting these requirements.

The "core" would be made a coordinated teaching exercise under conditions of surveillance by an appropriate body of the faculty so that the focus of teaching can be kept on topics that are pertinent to the education of physicians. Duplication as well as over- or underemphasis in certain areas will be held in check. The medical school is now using computers to study the present input in the education of medical students. Thus, much tediousness and repetition might be eliminated by alternative courses of study, each with considerable flexibility designed for the needs of different medical careers.

"Greater flexibility," Dr. Glaser said, "is necessary because of the undeniable upgrading in the quality of the entering student. Not only do we attract academically gifted students, but they arrive with considerably better preparation and more sophistication in the sciences than did the entering student of 8 to 10 years ago."

Presently at Stanford there are more than 300 young men and women studying to become physicians, and nearly 700 are in advanced programs such as internships, residencies, and postdoctoral fellowships.

Under the flexible plan, students will be admitted to Stanford medical school as candidates for the M.D. degree. The traditional classification of first, second, third, fourth, and fifth-year student will be abolished. Each student's study plans will be developed in consultation with faculty advisors.

This approach, the faculty expects, will help some students define their specialty interests early and shorten the length of their professional education. On the other hand, the plan will not interfere with the choice of those who prefer a standard course of medical education or those who desire early contact with patients.

The plan also recognizes the needs of medical students with respect to having a greater say about their school curriculum, Dr. Glaser said. Student representatives will be members of the faculty body responsible for curriculum review and development.

"Our faculty," he said, "welcomes the new intellectual restlessness. There are pressures on medical schools to educate more physicians. But increasing the number of doctors in training is not enough. We feel innovations are in order both in medical education and in the delivery of medical services."

STANFORD--Three new faculty appointments in the Department of Pathology have been announced by Stanford University School of Medicine.

The appointments, effective July 1, include Dr. Klaus G. Bensch, professor of pathology; Dr. Ronald F. Dorfman and Dr. Richard L. Kempson, both associate professors of pathology.

The appointment of the three new faculty members in pathology follows the selection of Dr. David Korn as professor and executive head of that department. The appointment of Dr. Korn, a pathologist and senior investigator in the National Institutes of Health, was announced last August and is also effective July 1.

Dr. Bensch received his M.D. degree in 1953 from Friedrich-Alexander University in Erlangen, Germany where he also served his internship. His residency in pathology was served at the University of Texas, where he was a Fulbright Fellow, and at Yale University School of Medicine.

Dr. Bensch has been a member of the Yale faculty since 1958 where he has been an associate professor of pathology since 1964.

Dr. Kempson received his medical education at Tulane University School of Medicine, graduating in 1955. Following his internship and residency, he was a National Institutes of Health fellow in surgical pathology at Washington University School of Medicine. He has remained on the faculty of that institution since 1963.

Dr. Kempson is a member of the American College of Pathology and the American Association for the Advancement of Science.

Dr. Dorfman received his medical education at the University of Witwatersrand Medical School in Johannesburg, South Africa and at the Post Graduate Medical School of London.

He was an intern and resident physician at Johannesburg General Hospital from 1949-50 and a senior resident physician at the Royal Victoria Hospital in Edinburgh, Scotland in 1952. He took additional training in clinical pathology at St. Mary Abbott's Group Laboratories in London for a year.

From 1955 to 1962, Dr. Dorfman served as a pathologist at the South African Institute for Medical Research.

He has been associated with Washington University School of Medicine since 1963, where he has been an assistant professor of pathology in the Division of Surgical Pathology since 1964.

Dr. Dorfman is a member of the International Academy of Pathology and the American Association of Pathologist and Bacteriologists.

STANFORD -- Stanford University will become sole owner of the present Palo Alto-Stanford Hospital July 1 under the terms of a revised agreement approved Thursday night (MAY 23) by the Palo Alto City Council in an 8-1 vote.

Adopted earlier by the Stanford Board of Trustees, the agreement will enable the University to own and operate the hospital for both community and Medical School patients. It also guarantees continued access to hospital facilities for all community physicians now on the staff.

The Mayor of Palo Alto and the President of Stanford's Board of Trustees still must sign a formal agreement to complete the transaction.

Under the terms approved by the City Council, Stanford will pay $1 million in cash, and assume $3.5 million worth of hospital construction bond payments over the next 20 years, and guarantee specified community hospital services for the next 40 years.

Besides increasing the initial cash payment from $500,000 to $1,000,000 and providing for arbitration, the revised agreement includes amendments requested by the City on a definition of hospital care to be provided, privileges for oral surgeons on the Palo Alto Medical Staff, and "courtesy staff" provisions for hospital departments.

In pledging the University's concern for the maintenance of patient care of the highest order, Dr. Robert J. Glaser, vice president for medical affairs and dean of the Medical School said: "We look forward to a productive and rewarding relationship between community physicians and faculty of the Medical School in providing superior health care for Palo Alto residents and others who seek the services of the new University hospital.

"We will move promptly to establish joint committees to deal with professional aspects of hospital operations and planning."

Terms agreed upon by the City and the University were based on a proposal submitted by University President Wallace Sterling last January.

Following several months of negotiations by represtatives of the City and the University, a proposal for the hospital sale was presented to the City Council April 22. The City Council amended the proposal and submitted it to the University Board of Trustees for approval.

The main points of the agreement are the guarantees it provides to the City in meeting its objectives with respect to health care of its citizens.

Palo Alto-Stanford Hospital has been owned jointly by the City and the University. Palo Alto has had access to 220 beds in the main 420-bed hospital and 150 beds in the nearby Hoover Pavilion. The City also has leased 32 acres of land from the University on which the facilities are located.

The City had expressed the desire "to get out of the hospital business." Stanford feels that a single ownership will enable its medical school to develop a true university hospital that is responsive to the emerging needs of medical education.

Under the terms of the agreement, Stanford will acquire Palo Alto's holdings and will operate the hospital, including the Hoover Pavilion. The University will grant staff privileges to all community physicians presently on the hospital staff for the remainder of their professional careers. A total of 370 beds now used by patients of community physicians will continue to be available to them. Palo Alto residents will be given admission priorities in non-emergency cases. STANFORD -- Mrs. Annabel Mann, 51, of Reno, Nevada, died early this morning at Palo-Alto Stanford Hospital from complications following a second kidney transplant by Stanford University surgeons.

Doctors said this morning that because of the high dose of immunosuppressives necessary to prevent rejection of the kidney, Mrs. Mann developed a variety of infections caused by organisms which normally would be suppressed by a healthy individual.

Mrs. Mann, who suffered chronic kidney failure, first received a kidney January 6 from Mrs. Virginia Mae White, who also was the donor in the heart transplant operation of Mike Kasperak. That kidney was not accepted by Mrs. Mann's body and was removed January 10.

On March 28, Mrs. Mann underwent surgery again for transplantation of a kidney from her sister, Mary Gibson, Chico. She had been a patient at the hospital since that time.

MXXX JBD:sc

Phoned to Associated Press
a.m. May 1, 1968

brief statement

At noon today surgeons completed a four and a half-hour transplant operation at the Palo Alto-Stanford Hospital.

The recipient is Joseph Rizor, a 40-year-old carpenter from Salinas, California.

The heart donor was a 43-year-old man who suffered irreversible brain damage. The donor's family has specified that his name remain anonymous.

Mr. Rizor was referred to Stanford by his family physician in March. He had suffered a serious heart condition for the past seven years.

Dr. Norman E. Shumway who headed the heart transplant team reported this afternoon that the patient's condition is fair, but that he is assisted in his breathing by artificial respiration because of a lung condition.

~~The Rizors~~

Bulletins ~~xxxxxxxxxxxx~~ on the patient's condition will be issued at 10:30 each morning or as the needx arises.

May 2, 1968

10:00 a.m.

Bulletin #1

Stanford University School of Medicine

Spokesmen at Palo Alto-Stanford Hospital disclosed this morning that a heart transplant is being performed by a team of surgeons from Stanford University School of Medicine, headed by Dr. Norman E. Shumway.

The recipient of the heart is a 40-year-old male and the donor is a 43-year-old male who suffered irreversible brain damage.

Further details will be issued by the medical center news bureau early this afternoon.

###

 FILE COPY

BULLETIN #2 Medical Center News Bureau, Stanford University

Surgeons at Palo Alto - Stanford Hospital today performed a heart transplant operation on a 40-year-old carpenter from Salinas, California.

The patient, Joseph Rizor, had suffered serious heart disease since 1961. He had three heart attacks and had developed irreparable heart muscle damage, doctors said. He is in fair condition. The patient has a lung condition and is assisted in his breathing by a respirator.

The new heart was transplanted in a four and a half hour operation from an anonymous donor who suffered irreversible brain damage, doctors said.

Rizor was referred to Stanford by his family physician for consideration as a potential recipient last March.

The operation was performed by a Stanford medical school surgical team headed by Dr. Norman E. Shumway.

Dr. Shumway who, with Dr. Richard Lower of the Medical College of Virginia, developed the techniques now used in heart transplantation, performed a transplant on Mike Kasperak January 6. Kasperak died 15 days later from what was described as "a galaxy of complications." His new heart functioned normally till the time of death.

At that time Dr. Shumway stated that these clinical trials would continue and that he hoped he would perform a series of transplants during the year.

He added that "heart transplantation cannot be termed therapy, at least not yet, therefore the recipient must be one whose death appears imminent or whole life so unbearable that he qualifies for this kind of clinical trial."

"It never entered my mind that Joe would be selected for a heart transplant," Mrs. Eileen Rizor said in an interview today.

"I remember his commenting, 'I wish that were me,' following the first heart transplant by Dr. Barnard in South Africa," Mrs. Rizor said. "At first I was shocked by the idea but time and the knowledge of how desperately my husband wanted to undergo that operation have made me realize that this may be his only chance to live."

Mrs. Rizor described her husband as an "outgoing, active and happy man" who had been immobilized by his heart ailment requiring that he remain in bed most of the time. A carpenter, who can "make anything" according to his wife, Rizor has been unable to work for the past two years.

Mr. and Mrs. Rizor will have been married 20 years in June. They have four children, Mark, 15, Michelle, 13, Judy, 7 and Christopher, 3.

Rizor was born in Belleveron, Pennsylvania. He has one sister, Mrs. William J. Belan of Cleveland, Ohio.

The Rizors have lived in Salinas for the past eight years. He is a member of the American Legion in Prunedale.

BULLETIN #3
Medical Center News Bureau
Stanford University School of Medicine

EDITORS: The following story is moved with the permission of the Anderson family, which requests no further interviews.

STANFORD: -- Rudy F. Anderson, an avid athlete, who was in excellent health and ran two miles every morning to stay that way at age 43, was the heart donor in Thursday's (May 2) transplant operation at the Palo Alto-Stanford Hospital. Mr. Anderson, a Pacific Telephone executive of 236 Bayview Dr., San Carlos, California, suffered a massive brain hemorrhage Monday night and died early Thursday morning.

Shortly thereafter, Stanford surgeons transplanted his heart into the body of Joseph Rizor, 40, of Salinas, California.

"Rudy took such good care of himself," said his wife, Margard (sq) (Maggie). I know he'd be very proud right now of what's happening at Stanford." He believed so in life."

The Andersons have two sons, Mark, 14, and Kurt, 10.

Mrs. Anderson said her husband was phoning a friend Monday night about 10 p.m. when he suddenly slumped to the floor. After their family doctor, Richard Carlson, and the neurosurgeon, Daniel Moub, told her there was no hope for her husband, and suggested a heart transplant, she gave her consent.

"Rudy bowled every week in the phone company league and had a 170 average," Mrs. Anderson said. "He was a fine swimmer and loved to hike. He loved everything outdoors and was a great competitor in everything he did. And every morning at 5:30 a.m. he got up to run two miles around the Carlmont High School track."

In addition to his personal enjoyment of good physical conditioning, Mr. Anderson, who "loved working with kids," had been a Little League manager for five years.

He was born in Oakland, and in Roosevelt and Fremont High Schools short played football, basketball, and was a hurdler and captain of the track team. At Hamilton Junior High School he had been student body president.

World War II interrupted his college plans, and he served in the Coast Guard, then in the merchant marine for a short time.

Other than a few years as a San Mateo fireman, Mr. Anderson had been with Pacific Telephone since 1949, serving in Palo Alto, Redwood City, San Jose (where he was manager of the business office), and in San Francisco since 1963. His most recent position was a results analyst in the commercial department.

He was a Mason, Scottish Rite, and Shriner.

10:30 a.m.

Heart transplant patient Joseph Rizer continues to be in fair condition this morning. His lung condition, however, which has been a source of concern to Stanford doctors remains unchanged. Because of his long-standing heart condition, Mr. Rizer has severe lung disease which makes it difficult for his blood to pick up enough oxygen as it travels through the lungs. The patient is assisted in breathing by a respirator.

His new heart continues to react very well, doctors say. His blood pressure, pulse, and heart output are normal. The patient is awake and alert. Mrs. Rizer visited him this morning.

The lung condition which has been a source of concern to doctors treating heart transplant patient Joseph Rizzo has improved slightly this morning. Doctors at Stanford are encouraged by his progress. The patient continues to be in fair condition. He is still being aided in breathing by a respirator. His new heart continues to function normally.

For a brief period this morning, when Mr. Rizzo was off the respirator, he joked with doctors and expressed a desire for something "stronger than apple juice" to drink. He is now on a liquid diet of soups and juices. He was visited by his wife yesterday afternoon and this morning.

The next bulletin will be issued Monday at 10:30 a.m.

Sunday

May 5, 1968

6:00 p.m.

Heart transplant patient Joseph Rizor suffered a major setback at 2:00 p.m. today, Sunday, May 5th, when his new heart suddenly stopped for a few minutes because of a lung complication.

Doctors restarted the heart but his condition is critical.

The heart stoppage was caused by a lack of oxygen. Because of Rizor's severe lung disease, doctors explained, he is getting only 10 per cent of a normal oxygen requirement. Since the transplant May 2, Rizor's condition has been listed as fair, with the exception of his lung disease which has been a continuing source of concern.

Rizor, a 40-year-old carpenter from Salinas, received a new heart from Rudolph F. Anderson, a 43-year-old Pacific Telephone executive who died from a massive brain hemorrhage.

Joseph Rizor, who received a new heart at Palo Alto-Stanford Hospital last Thursday, died at 8:30 p.m. PST today because his heart was not getting enough oxygen.

Rizor suffered a major setback at 2 p.m. when his heart, which had been beating strongly, suddenly stopped for a few minutes because of a lung complication.

Doctors restarted the heart, but death came 6½ hours later.

Because of Rizor's severe lung disease, doctors explained, he was getting only about 10 per cent of a normal oxygen requirement. Since the transplant May 2, his condition had been listed as fair, with the exception of the lung disease, which was a continuing source of concern.

Twenty-four hours after the operation, Dr. Norman E. Shumway, head of the surgical team which performed the transplant, said "for the next few days we can say that his condition will be critical until we can see some change in the level of oxygen tension in his arterial blood."

Rizor, 40, of Salinas, Calif., received his new heart last Thursday from Rudolph F. Anderson, 43, of San Carlos, Calif.

Rizor is survived by his wife, Eileen, four children, and a sister, Mrs. William J. Belan of Cleveland, Ohio.

BULLETIN #9

Medical Center News Bureau
Stanford University School of Medicine

Monday
May 6, 1968
2:30 p.m.

STANFORD -- An autopsy report released today has confirmed that heart transplant patient Joseph Rizor died of complications from severe lung disease.

The preliminary post-mortem finding show that the 40-year-old Salinas (Calif.) carpenter had severe patchy sclerosis (hardening) of both main pulmonary arteries extending well down into the minor pulmonary arterial system.

Resistance caused by the hardening of these arteries made blood travel through the lungs without picking up normal amounts of oxygen.

The condition of the lungs, doctors explained, is a common result of prolonged heart failure. Rizor first developed heart failure in 1961.

The post-mortem findings show no signs of graft rejection, doctors said. They added, however, that because the patient survived only 3-1/2 days, no signs of rejection were expected.

Asked if the recent transplant has caused him to revise his views on selection of potential recipients, Dr. Norman E. Shumway, head of the surgical team, noted that "with a wider usage of heart transplants, the procedure will be extended to a group of patients who are not as far advanced in the course of their disease as those we have seen."

"At present we are dealing with patients who face certain death if nothing is done and, therefore, there is a justification for this kind of attempt," Dr. Shumway said.

He added the program at Stanford will continue "as we see other types of patients who qualify as heart recipients."

STANFORD--Members of the department of psychiatry at Stanford University School of Medicine today announced the formation of a Committee on Violence.

"It is imperative," said the co-chairmen, Dr. David N. Daniels and Dr. Frank M. Ochberg, "for psychiatrists to contribute to the solution of the crisis issue of violence in America."

The committee's purpose, they said, is to review intensively the various aspects of violence relating to behavioral issues, and to prepare a report that would be relevant to the President's Commission on Violence and to concerned lawmakers, citizens, organizations, and other professional groups within the mental health field.

Six different aspects of violence will be reviewed: (1) mental illness and violence, (2) mass media and violence and the American character, (3) conflict resolution and the choice of violence, (4) the phenomenon of assassination, (5) firearms and violence, and (6) resistance and counter-arguments to gun control.

A report by the committee will be issued within the next two months. It will include pertinent background information as well as specific proposals and recommendations for action and further long-range study.

"We would welcome contact with other groups interested in the crisis of violence," the co-chairmen said. Drs. Daniels and Ochberg can be contacted at the department of psychiatry at the Medical School.

Other faculty members, residents and fellows from the psychiatry department on the committee are Dr. John Adams, Dr. Peter Bourne, Dr. Paxton Cady, Dr. J. Chris Gillin, Dr. Marshall Gilula, Dr. George Gulevich, Dr. Beatrix Hamburg, Dr. Jon Heiser, Dr. Frederic Ilfeld, Dr. Jay Jackman, Dr. P. Herbert Leiderman, Dr. Walton T. Roth, Dr. Alberta Siegel, Dr. Robert Taylor, Dr. Jered Tinklenberg, Dr. E. Fuller Torrey, Dr. Ed Trickett, and Dr. Alfred Weisz.

STANFORD -- Stanford University School of Medicine presented awards to eight graduating students at the annual senior class convocation Sunday (JUNE 15).

Degrees were presented to 55 men and 6 women, members of the fifth class to complete Stanford's five-year medical curriculum. The five-year program was inaugurated when the Medical School moved from San Francisco to the Stanford campus in 1959.

At the convocation, Michael B. Marchildon received the Dr. and Mrs. Joseph Fife Surgery Award, given annually to the outstanding student in surgery.

Receiving the Robert H. Alway Book Award was Fred H. Burbank. The Book Award, named in honor of Dr. Alway, Dean of the Medical School from 1958 to 1964, is given to a student who has "availed himself especially well of the Stanford five-year plan."

Paul R. Bergstresser received the L. A. and Marian S. Hopkins Award in Dermatology. Receiving the Lowell A. Rantz Memorial Award to the student "who has distinguished himself in the field of infectious diseases" was Carl O'Neal Page, Jr.

The Harold K. Faber Pediatric Award was presented to Douglas P. Tustin. This award honors potential contributors to child health in recognition of accomplishments in pediatrics.

Richard H. Lanzerotti received the Borden Undergraduate Research Award in Medicine, given by The Borden Company Foundation, Inc., to the senior student who has completed the "most meritorious" research during his medical training.

Receiving the National Foundation Merit Award for outstanding research in the area of birth defects was Ronald Levy, and William G. Hayden received the Upjohn Achievement Award for outstanding clinical performance.

Dr. LeRoy A. Pesch, associate dean for student affairs and professor of medicine, presented the awards, and Dr. Harold K. Faber, emeritus professor of pediatrics, announced the recipients of the award named in his honor.

-more-

Class President William G. Hayden presented the annual Arthur L. Bloomfield Award for excellence in the teaching of clinical medicine to Dr. Allen B. Barbour, assistant professor of medicine and head of the division of ambulatory medicine.

Dr. Halsted R. Holman, Guggenhime Professor and executive head of the department of medicine, delivered the faculty address, and Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, administered the Hippocratic Oath and presented diplomas to the Class of 1968.

Award winners and their parents' names and addresses are listed below:

CALIF., LA JOLLA--Fred H. Burbank, Mr. and Mrs. Forrest Burbank, 1365 W. Muirlands Dr.

PALO ALTO--Ronald Levy, Mr. and Mrs. Herman Levy, 420 Hale St.

PEBBLE BEACH--Douglas P. Tustin, Mrs. Margaret Miller, Box 2069.

ILL., CARLINVILLE--Richard H. Lanzerotti, Mr. and Mrs. Emanuel Lanzerotti, 801 High St.

WEST FRANKFORT--Michael B. Marchildon, Mr. and Mrs. C. A. Marchildon, 606 E. St. Louis St.

NEW MEX., LOS ALAMOS--Paul R. Bergstresser, Mr. and Mrs. Karl Bergstresser, 739-42nd St.

PENN., DUSHORE--William Hayden, nephew of Mrs. Agnes Hochberg (parents deceased).

S.C., CHESNEE--Carl O'Neal Page, Jr., Rev. and Mrs. Carl O. Page, Route 2.

STANFORD--Dr. Jack D. Barchas, assistant professor of psychiatry at Stanford University School of Medicine, has been awarded first place honors in the 1968 A.E. Bennett Neuropsychiatric Research Foundation contest for his study on the formation and metabolism of adrenalin in the brain of mammals.

Announcement of the award was made today (JUNE 14) at the convention and scientific meeting of the Society of Biological Psychiatry, sponsors of the contest, in Washington, D.C.

Co-authors of the two-year study on rats and sharing the award with Dr. Barchas were Roland Ciaranello of Schenectady, New York, and Alan M. Steinman of Los Angeles, third and second year medical students, respectively, at Stanford.

The awards by the Society are made to young investigators under the age of 35 "to stimulate the entrance of young scientists into research in psychiatry and related fields."

"It has been known for some time that small amounts of adrenalin are present in the brain," Dr. Barchas says. Our research on rats has shown that while some adrenalin is pumped to the brain in the blood supply, there is an additional amount produced independently of the adrenal gland by an enzyme in the brain. This production is localized in certain, basal areas of the brain which control emotional and physiological processes."

"We also found that the brain metabolizes and utilizes adrenalin very quickly--in around three hours," he says.

"These facts indicate that adrenalin may have a role in abnormal or normal functioning of the brain and in behavior," according to Dr. Barchas.

Dr. Barchas received his M.D. degree in 1961 from Yale Medical School. He served his internship at the University of Chicago. After completing his residency at Stanford in 1967, he joined the faculty here.

Ciaranello received a B.S. degree from Union College in 1965. Steinman was awarded a S.B. degree from M.I.T. in 1966.

Lives of three Santa Clara County residents and a 10-year old boy from Salinas are being sustained on a new hemodialysis unit at Stanford University School of Medicine while they await kidney transplants.

Opening of the unit marks the continuing expansion of the kidney transplant program at Stanford although members of the Department of Surgery are concerned about the program's future.

"The very existence and expansion of the kidney transplant program at Stanford depends both on public support in donating organs and on cooperation from public officials, who must give permission for the transplant even after consent has been obtained from the donor's family," Dr.Roy Cohn, professor of surgery and head of the renal transplant programs, says. "This applies equally to the transplantation of other organs--the heart, liver and cornea."

Dr. Cohn, his associate, Dr. Zoltan Lucas, assistant professor of surgery, and Dr. John Palmer, assistant professor of surgery, spoke this morning at the opening of the new dialysis unit at the Medical School.

"We can continue temporarily to substitute the function of the kidney in cleansing these patient's systems of wastes and poisons by dialysis," Dr. Palmer, who heads the dialysis unit, said. "But whether they will live or die depends on the donation of a kidney by individuals unrelated to the patients or donation of a cadaver kidney by members of a deceased person's family."

None of the Santa Clara county residents or the young boy now at Stanford has a relative who is able or suitable for donation of a kidney. All have been waiting several months for kidney transplant.

The problem of public support and understanding seems less difficult than that of cooperation from public officials.

Dr. Cohn pointed out that Stanford has faced consistent difficulties in obtaining not only cadaver kidneys but also heart valves and corneas for transplant from the Coroner's Office in Santa Clara County.

Twice in recent weeks the Coroner's Office has refused to allow use of a

donor's kidneys. In both instances families of the fatally injured individuals had requested that kidneys be donated to save the lives of others.

"The problem appears to be one of jurisdiction and interpretation of the state law by this county's Coroner's Office as opposed to other counties. "Dr. Cohn said. "It is also illustrative of the difficulties faced by both patients and doctors because of differences of opinion among county coroners."

He pointed out that both UC and UCLA have active cadaver kidney transplant programs. The Coroner's Office in the respective counties of these two medical centers are governed by the same law as that of Santa Clara County.

"If nothing is done to bring about a more enlightened attitude, our cadaver kidney transplant program may have to be dropped," Dr. Cohn said.

One of those awaiting kidney transplantation at Stanford is a blond, freckled, 10-year old boy, Clifton Henry, Jr. of Salinas. He is the son of Mr. and Mrs. Clifton Henry.

According to Dr. Lucas, the boy suffers from a rare condition called anti-glomerular basement membrane disease. There are only two recorded cases in medical literature. The disease appears after a strep throat infection.

Cliff received a healthy kidney from his father five months ago at Stanford, but it too developed the disease that damaged the boy's own kidney one month after the transplant. Since then, the patient has been on an artificial kidney machine.

"By an accident of nature," Dr. Lucas explained, "the antibody produced by the body against strep bacteria is the same antibody which destroyed the boy's kidney and his first transplant. We need to know now if this antibody is still present in his circulation before we attempt another transplant."

Surgeons plan to learn if a second transplant on Clifton is possible by using a donated kidney to test his circulation for anti-kidney antibody.

The test is done by connecting the kidney outside the patient's body in place of the artificial kidney. After the patient's blood circulates through the kidney for 48 hours, it is removed and examined under the microscope. Absence of tissue damage indicates that antibody is no longer present.

"We then would be able to perform a second transplant on Clifford to save his life," Dr. Lucas said.

STANFORD--Seven fifth-year and two fourth-year medical students at Stanford University School of Medicine have been elected to Alpha Omega Alpha, the national honor medical society.

New members from the fifth year class are Stephen C. Adler, Thomas H. Brzozowski, Carl David Erickson, John W. Griffin, Michael B. Marchildon, Carl O'Neal Page, Jr., and Maria V. Smith. Elected from the fourth-year class were Ronald D. Adler and Virginia J. Borson.

Medical students are elected to Alpha Omega Alpha on the basis of scholarship and potential leadership. To qualify, they must be fourth or fifth year students.

Also selected to membership in the Society was Dr. Gunther W. Nagel, clinical professor of surgery emeritus, and director of alumni relations at the Medical School.

The charter of Alpha Omega Alpha allows for the election to membership of physicians who, although not students, have made significant contributions to the profession.

Dr. Nagel received his A.B. (1917) and M.D. (1921) degrees from Stanford University. He was a Fellow at the Mayo Clinic in Rochester, Minn. for six years and during this time he was awarded an M.S. degree in surgery from the University of Minnesota. He practiced surgery in Francisco and taught many classes of Stanford medical students from 1929 until his retirement.

Dr. Nagel has published numerous scientific papers dealing with gastrointestinal surgery and most recently a book, THE MAYO LEGACY.

Students and their parents' names and addresses are listed below:

CALIF., Berkeley -- Virginia J. Borson, Dr. and Mrs. H. J. Borson, 244 Alvarado Rd.
Los Altos --Ronald D. Adler, Mr. and Mrs. Hans G. Adler, 23156 Payne Ct.
Oakland -- Maria Viola Smith, Mr. and Mrs. Vito Viola, 12669 Skyline Blvd.
Pasadena -- Carl David Erickson, Mr. and Mrs. Carl A. Erickson, 1371 Inverness Dr.

ILL., West Frankfort -- Michael B. Marchildon, Mr. and Mrs. C. A. Marchildon, 606 E. St. Louis St.

NEB., Lincoln -- John W. Griffin, Mr. and Mrs. A. W. Griffin, 4627 "A" St.

N.Y., Gouverneur -- Stephen C. Adler, Dr. and Mrs. Ernest L. Adler, 209 E. Main St.

S.C., Chesnee -- Carl O'Neal Page, Jr., Rev. and Mrs. Carl O. Page, Route 2.

WYO., Laramie -- Thomas H. Brozozowski, Mr. and Mrs. Joseph S. Brozozowski, 200 Grays Gables Rd., #30.

STANFORD--Dr. William H. Clark of Palo Alto is the new president of the Stanford Medical Alumni Association, and Dr. Lawrence E. Heiges of Lompoc is its new president-elect.

Dr. Clark, a specialist in internal medicine, succeeds Dr. Robert M. Shelton of Pasadena. He will serve as president of the Association through June, 1969.

Dr. Clark holds both A.B. and M.D. degrees from Stanford, graduating from the Medical School with the Class of 1944. A partner in the Palo Alto Medical Clinic, Dr. Clark is also a clinical associate professor of medicine at Stanford University School of Medicine and has served as chief of the Palo Alto Medical Staff. He is a member of the Santa Clara County Medical Society and has been a delegate to the California Medical Association meeting since 1958.

The new president has also been active in civic affairs. He is a past-president of the Palo Alto Rotary Club and served on the board of directors for the Chamber of Commerce. Other interests include United Crusade and Boy Scout activities. Dr. Clark is presently serving on the Palo Alto City Council.

Dr. Heiges has been in general practice in Lompoc since his graduation from Stanford University School of Medicine in 1933. He also received an A.B. from Stanford in 1929.

Dr. Heiges has devoted considerable time to the blood bank program in California. A past-president of the Santa Barbara County Medical Society, he was instrumental in the establishment of the Tri-County Blood Bank for Santa Barbara, Ventura, and San Luis Obispo counties. He has also served on the board of directors for both the California Blood Bank System and the American Association of Blood Banks. Other activities include past-president of the Lompoc Rotary Club and a member of the board of directors of both the Lompoc Boys' Club and Boy Scout programs.

Other newly elected members of the board of governors of the alumni association are Dr. Paul Campbell, '49, Portland; Dr. Robert E. Berner, '44, Palo Alto; Dr. Howard B. Kirtland, Jr., '44, San Diego; Dr. George J. Laird, '40, Burlingame; and Dr. Leo Nannini, '38, Reno.

Dr. David A. Rytand of Atherton, Bloomfield professor of medicine at Stanford University School of Medicine, was re-elected secretary-treasurer.

Dr. LeRoy A. Pesch has resigned as associate dean at Stanford University School of Medicine, to become dean of the School of Medicine and director of University Hospitals at the State University of Buffalo.

Dr. Pesch has been professor of medicine and associate dean at Stanford since 1966. He headed the admissions committee and served as chairman of the committee on medical education which developed a further revision to the Stanford curriculum. The proposed elective curriculum will allow each medical student to develop a study program that will meet his individual objectives in the field of medicine.

The 37-year-old physician was also involved in the Stanford program in community health. He worked with a faculty committee to develop neighborhood health centers in East Palo Alto and Alviso.

Dr. Pesch is a graduate of Iowa State University and the Washington University School of Medicine, St. Louis, Mo. He was an assistant professor of medicine at Yale University. He spent several years as a research associate in biochemistry at the National Institute of Arthritis and Metabolic Diseases, Bethesda, Md., and helped establish a new School of Medicine at Rutgers University. He is known for significant research contributions in the field of liver diseases.

STANFORD--Dr. John L. Wilson, 54, has been appointed associate dean and director of Regional Medical Programs at Stanford University School of Medicine. He will also serve as professor of surgery.

He will plan the groundwork for cooperative medical programs related to heart disease, cancer, and stroke in Stanford's assigned region. This includes the counties of Calaveras, Mariposa, Merced, Monterey, San Benito, San Joaquin, San Mateo, Santa Clara, Santa Cruz, Stanislaus, and Tuolumne.

Dr. Wilson has served as dean of the Faculties of Medical Sciences at the American University of Beirut since 1966. He was also professor and chairman of the Department of Surgery there since 1953. As an associate clinical professor of surgery at the University of California Medical Center in 1958, Dr. Wilson served a two-year stint as chief of the Surgical Service at San Francisco Veterans Administration Hospital.

His appointment, announced today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, is effective immediately.

Dr. Glaser also announced the appointments of two associate directors for the regional medical program, Dr. R. L. Scotte Doggett, 37, assistant professor of radiology, and Dr. William C. Fowkes, 38, assistant professor of medicine.

Dr. Doggett has been on the Stanford faculty since 1964. Dr. Fowkes has been on the volunteer faculty since 1965 and has been associated with the El Camino Internal Medical Group. Both are Stanford medical school graduates and have received their specialty training at Stanford University Hospital. Dr. Doggett will serve as program coordinator for cancer programs, and Dr. Fowkes will be coordinator for programs in cardiology.

-more-

The group's initial work will be to determine how the Stanford region can realize the humanitarian and scientific potential of the concepts embodied in Public Law 89-239 for Regional Medical Programs for "Heart Disease, Cancer, Stroke and Related Diseases."

The planning effort is funded for two years by a $586,000 grant from the National Institutes of Health and is administered through the California Committee on Regional Medical Programs.

Stanford's role, according to Dr. Glaser, will be primarily educational. For doctors, nurses, and other health care personnel, the medical programs will emphasize continuing education in advanced techniques. Also stressed will be better communication and more cooperation between doctors, the Stanford University Medical Center, and community hospitals in the eleven-county area. The objective of all this is to shorten the gap between medical science and medical service and bring excellent care within the reach of all citizens.

Dr. Wilson, a native of Sturgis, Kentucky, received the B.A. from Vanderbilt University in 1935, and the M.D. from Harvard Medical School in 1939. He interned at Massachusetts General Hospital in Boston where he also specialized in thoracic surgery. He has held academic appointments at Stanford University School of Medicine (1949-52) and Washington University School of Medicine in St. Louis, Mo. (1952-53).

He is a member of numerous professional and honor societies including Alpha Omega Alpha, the national honor medical society. He is recipient of the Order of Merit of the Republic of Lebanon (1955), and Superior Performance Award of the U.S. Veterans Administration Hospital (1960).

Dr. and Mrs. Wilson have four sons and a daughter.

STANFORD--Dr. Keith F. Killam, Jr., professor of pharmacology at Stanford University School of Medicine, has been appointed chairman of the department of pharmacology at the University of California at Davis.

A former special consultant to the President's Advisory Commission on Narcotic and Drug Abuse, Dr. Killam is noted for his research on the effect of depressants, stimulants, hallucinogens and psychotherapeutic agents on the central nervous system. He is also actively involved in studies of an animal model of human epilepsy to further understanding of the disease process and to search for new therapeutic agents in treating the disease.

He has also served as a consultant to the U.S. Air Force and the National Science Foundation and has been a member of the advisory committee for the California State Department of Mental Hygiene Research.

Dr. Killam received a B.S. degree in 1948 from Tufts College. He was awarded an M.S. degree in 1952 and a Ph.D. degree in 1954, both in pharmacology, from the University of Illinois Graduate Professional Colleges. He is a member of numerous professional organizations.

Dr. Killam has been a member of the Stanford Faculty since 1959. He and his wife and their three children will move to Davis in August.

STANFORD--Stanford University School of Medicine has been awarded a five-year grant totaling $500,000 to expand and strengthen its program of medical education and teaching.

The grant is part of $10 million awarded to 30 private medical schools in the country by the Richard King Mellon Charitable Trusts. Ten of the schools, including Stanford, will receive $100,000 each year for the next five years. Twenty others will receive $50,000 each year for the same period.

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, said that the grant "will enable us to meet a critical need in academic medicine today--that of increasing the number and enhancing the caliber of junior faculty members."

"It is of paramount importance to attract qualified young men and women to enter full-time careers in teaching. This addition to our existing funds will help us to recruit and support promising young physicians and medical scientists."

In announcing the $10 million grant, the board of trustees of the Richard King Mellon Charitable Trusts said:

"One of the most serious problems in our medical schools today is the need for money with which to pay adequate salaries for competent teachers on permanent faculty staffs.... The trustees hope that the grants will enable the 30 schools to maintain and improve the quality of their faculties...."

The $10 million grant makes a total of more than $57 million that has been contributed to medicine through grants and gifts by Lieutenant General and Mrs. Richard King Mellon since 1945. General Mellon, Pittsburgh, Pa. financier, is a governor and president of T. Mellon & Sons, investment management firm.

STANFORD--Major improvements in wage and fringe benefits for employees of Stanford University Hospital and upward adjustments of some hospital charges were endorsed by the Hospital board at its first meeting Monday (JULY 8).

In a letter to all Hospital employees, Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine pointed out that increased wage scales and shift differentials have been put into effect. The Hospital will also provide for increased health and dental insurance benefits during the year.

Dr. Glaser pointed out that the wage and benefit improvements "are based on the realities of today's economy and take into account the high standard of excellence established by Stanford University Hospital personnel."

Also approved by the Board were increases in the Hospital's daily service charges, on the order of $3 to $4 a day for medical and surgical patients. The new rates will go into effect Aug. 1.

"The continual rise in the cost of materials and employee compensation and the pressing need for major equipment items have made an increase in operating revenues necessary," Dr. Glaser said. "We are vigorously involved in research aimed at developing operating and administrative innovations which, we anticipate, will lead the way to a slowing of the hospital-cost spiral."

The rate increase approved by the new Board is less than the $4-$5 increase projected earlier as necessary.

STANFORD--Dr. Thomas A. Gonda, associate dean of Stanford University School of Medicine, has been appointed acting director of Stanford University Hospital.

Announcement of Dr. Gonda's appointment was made by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, following the first meeting Monday (JULY 8) of the new board of the University Hospital. Also announced were the appointments of Courtney S. Jones as acting deputy director and James H. Stanford as associate director of the Hospital.

Dr. LeRoy E. Bates, former director of the Palo Alto-Stanford Hospital Center, will serve as a consultant to the new hospital on administrative matters and special projects.

According to Dr. Gonda, other members of the administrative team of the Palo Alto-Stanford Hospital Center will continue to carry out their former duties and responsibilities.

Dr. Gonda expressed pleasure that the distinguished citizens appointed to the new hospital board had agreed to serve. "The experience and dedication of the board members will be important to operation of the new University Hospital," he said.

Dr. Gonda, in addition to his administrative offices, is also a professor of psychiatry, having joined the Medical School faculty in 1954. He received both his A.B. (1942) and M.D. (1945) degrees from Stanford.

Jones, acting deputy director of the University Hospital, is director of business and fiscal affairs at the Medical School. Former assistant controller and associate director of the University's computation center, he received his Bachelor's degree in mathematics from Brown University and his Master's degree in business administration from Stanford.

Stanford, an expert in administrative systems, comes to the Hospital staff from the Medical Facilities Planning Group of the Medical School. Prior to joining the University staff last fall, he served as assistant to the financial vice-president of General Mills, Inc. Stanford received an A.B. degree from Stanford as well as a Master's degree in business administration.

STANFORD--The search for the cause and cure of psoriasis, the disfiguring skin disease that afflicts four to six million Americans, will be continued at Stanford University School of Medicine under a three-year grant of $225,824 from the John A. Hartford Foundation, Inc., of New York City.

Announcement of the grant was made jointly today by Ralph W. Burger, president of the Foundation, and Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine. Psoriasis research at Stanford has been supported by the Foundation since 1959.

Investigation at Stanford of psoriasis, which produces reddened, scaly spots or patches on many parts of the body, indicates that onset of the disease is initiated by a kind of local chemical alteration of the skin. With all the assembled knowledge of this reaction, scientists still cannot explain its basic nature.

"Our studies suggest that the basic abnormality lies not in the fundamental nature of growing cells, but in a defect in the mechanism which controls growth of the epidermis, the outer layer of the skin," says Dr. Eugene M. Farber, professor and executive head of the Department of Dermatology. "We believe that the degree of growth alteration may be different in different psoriatic lesions."

"The grant from the Hartford Foundation will enable us to continue this important and promising area of research," he said.

Research will also continue in the use of new drugs and other forms of treatment for psoriasis. Although no real "cure" for psoriasis can be claimed, in 38.5 per cent of the patients, the disease may temporarily disappear spontaneously or with known therapy.

"The failure of any therapy to effect a permanent cure indicates that known drugs achieve their temporary success by inhibiting growth of the outer skin layer, but not by removing the predisposition of the skin to psoriasis," Dr. Farber stresses.

Stanford researchers have studied over 2100 cases of psoriasis through a patient questionnaire to learn more about the cause of the illness, what its specific characteristics are, and how it relates to other diseases.

Computerized results of the survey show that there are influences in the incidence of psoriasis related to age, family, race, and locality. They indicate specifically that:

-more-

--Inheritance figures prominently in the incidence of the disease. Eighteen per cent of the patients who took part in the questionnaire reported a parent with psoriasis, 11 per cent reported a brother or sister, and 13 per cent identified more distantly affected relatives.

--For patients with a genetic predisposition, skin injury may trigger psoriasis. Fourteen per cent of the patients said their psoriasis began at a site of an injury.

--Climate is a factor in the disease. Of the patients studied, 77 per cent reported their skin improved in hot weather and 88 per cent noted it was worse in cold weather. Seventy-eight per cent stated sunlight caused improvement, and 15 per cent reported their skin got worse on exposure to sunlight.

--Emotional factors were thought to have aggravated the disease in 40 per cent of the patients.

Research has also confirmed a strong link between psoriasis and arthritis. Of the patients studied, 25 per cent had arthritis of various joints, and 65 per cent said psoriasis had preceded arthritis.

"Investigation of the relationship between these two diseases, plus the familial aspects of psoriasis will be continued," according to Dr. Farber, "as well as study of the possible effects which psoriasis has on other systems of the body."

The grant money will also be used to establish an international information and coordination center at Stanford for the study of psoriasis.

"Since centers of interest in psoriasis are scattered throughout the world, it is very difficult for any investigator to keep abreast of both positive and negative results of research going on elsewhere," Dr. Farber said. "A center for the accumulation, coordination and distribution of detailed information on all research activity relative to psoriasis throughout the world will do much to eliminate this problem."

FOR IMMEDIATE RELEASE

STANFORD - Dr. Robert J. Glaser, 49, vice president for medical affairs and dean of the Stanford University School of Medicine, Tuesday (JULY 8) was named acting president of the University.

His selection was announced by W. Parmer Fuller III, president of the Board of Trustees. The appointment is effective Sept. 1, 1968, upon the retirement of President J.E. Wallace Sterling. Last year, Sterling announced his intention to retire not later than Sept. 1, following 19 years service in the University's top administrative post.

Dr. Glaser will be assisted in his new assignment by Vice President and Provost Richard W. Lyman, who will continue as chief academic officer under the president, as well as by other members of the president's staff.

Former president of the Affiliated Hospitals Center in Boston and professor of social medicine at Harvard Medical School, Dr. Glaser came to Stanford as vice president in 1965.

He has headed the University's complex and lengthy negotiations for purchase of the City of Palo Alto's share of Palo Alto-Stanford Hospital, completed earlier this month.

President-elect of the Association of American Medical Colleges, Dr. Glaser was appointed to a 15-man National Advisory Committee on Higher Education last year to explore relationships between colleges, universities, and the federal government.

He also is a member of a 21-man Board of Medicine established by the National Academy of Sciences last year to speed the benefits of medical research and practice to the public.

Under his leadership, the School has received a two-year planning grant of more than $500,000 from the National Institutes of Health to develop a cooperative program for improving the diagnosis and treatment of heart disease, cancer, stroke, and related diseases.

It also has received a $500,000 grant from the Commonwealth Fund of New York to initiate planning for a new hospital and ambulatory care center to advance fundamental reforms in hospital services and education in the health professions.

Earlier this year, Dr. Glaser announced faculty approval of major changes in the Medical School curriculum to allow students to become physicians in the flexible atmosphere of a graduate school. He has tought freshman seminars for undergraduates at the University.

While serving as acting president, he will continue to devote a part of his time to Medical Center affairs.

Educated in the public schools of St. Louis and University City, Mo., Dr. Glaser received his S.B. degree at Harvard in 1940 and his M.D. magna cum laude there in 1943.

After serving his internship and residency at the Barnes Hospital and the Peter Bent Brigham Hospital, he rose steadily through the ranks at Washington University, St.Louis, where he served as associate dean of the Medical School from 1955 to 1957.

He then moved to the University of Colorado as dean of the School of Medicine, becoming vice president for medical affairs before returning to Boston in 1963.

He is married to the former Helen L. Hofsommer (M.D.). They have three children: Sally Louise (born 9/5/50), Joseph II (1/22/52), and Robert Joy Jr. (8/1/53). ### 7/8/68

STANFORD--Stanford University President Wallace Sterling and Palo Alto Mayor Frances Dias today signed final legal documents for the sale of the City's share of the Palo Alto-Stanford Hospital Center to the University.

The documents were signed in a brief ceremony held at the Stanford University School of Medicine.

President Sterling also announced the appointment of nine distinguished citizens of the area to the Board of the Stanford University Hospital, the new name for the combined hospital unit.

They are: Mrs. Edward Heller, Atherton, long active in area cultural, educational, and community activities and currently vice-chairman of the Board of Regents of the University of California; Kirk Jeffrey, Palo Alto, president of the Stanford Bank; Robert Klein, Portola Valley, a financial consultant; John A. Minor, Menlo Park, superintendent for Ravenswood City School District; James E. O'Brien, Palo Alto, vice-president and general counsel, Standard Oil Company of California; Raymond F. Rohrs, Palo Alto, a former Palo Alto city councilman and owner of The Clothes Closet; John Santana, Jr., Palo Alto, vice-president of the Peninsula Creamery; John A. Stern, Palo Alto, an executive of United Air Lines; and Dr. Alejandro Zaffaroni, Atherton, president of Alza Corporation, an outgrowth of Syntex Corporation of which Dr. Zaffaroni was formerly president.

Mrs. Heller, Jeffrey, Klein, O'Brien, Santana, Stern, and Zaffaroni have been members of the current Palo Alto-Stanford Hospital Board of Directors. Rohrs served on the hospital board in 1960-61.

President Sterling pointed out that the incorporation of a number of board members of the Palo Alto-Stanford Hospital into the new Board will "lend continuity to the organization of the new Board and the operation of the new University Hospital."

Sale of the Hospital to Stanford culminates several years of discussion between the City and the University. The terms that form the basis of the final agreement were orginally presented in a letter to the City by President Sterling in January 1968. After prolonged negotiations, agreement was reached and accepted by the Palo Alto City Council in May.

The University's Board of Trustees has authorized the designation of the entire Hospital Center, including both the Hospital and the Medical School, as the Stanford University Medical Center.

STANFORD - - A 51-year-old Palo Alto engineer Saturday became the fourth patient to receive a new heart at Stanford University Hospital.

The recipient, Robert O. McKee of 3980 El Camino Real, received his new heart in a 4½ hour operation by a team of surgeons led by Dr. Norman E. Shumway, professor and head of the division of cardiovascular surgery at Stanford University School of Medicine. The operation was completed at 12 noon.

McKee is listed in satisfactory condition.

The heart donor, Dr. William Sample, 39, of 2101 Harkins, Menlo Park, was chief psychiatric social worker and acting director of the Children's Health Council in Palo Alto. He died this morning at Stanford University Hospital of a massive brain hemhorrage he suffered Friday evening.

Dr. Sample was born in Bixby, Oklahoma and held the M.A. and Ph.D. degrees in social work from the University of Chicago. He had been with the Children's Health Council since 1966. Dr. Sample is survived by his wife, Elizabeth of Menlo Park, his mother, Mrs. Dora Cantner of Bixby, and three sisters.

McKee was employed in the Spinco Division of Beckman Instruments, Palo Alto, as a manufacturing methods engineer until he resigned 10 months ago because of ill health. He had suffered from chronic heart failure as a result of severe coronary artery disease for the past three years.

McKee has four children--three from a previous marriage. Mrs. McKee is in seclusion and was unavailable for comment.

Meanwhile, Leonard Drake, the 42-year-old retired postal clerk from Eugene, Oregon, who received a new heart at Stanford eight days ago, was reported recovering satisfactorily this morning. Drake spent most of the day yesterday out of bed, doing exercises from time to time to keep his muscles and lungs in full use. His heart function is reported normal.

STANFORD--Stanford heart transplant patient William Karraker, 50, of Stockton, died unexpectedly early this morning at St. Joseph's Hospital in Stockton.

Mr. Karraker, who received a transplanted heart Nov. 22, 1968, was admitted to St. Joseph's Hospital Friday for observation when his pulse rate became irregular.

Cause of death is undetermined, pending an autopsy.

Mr. Karraker is survived by his wife, Marty, and four children, ValRae, 23, Perry, 21, Mendy, 15, and Katherine, 11.

STANFORD--Talks on transplant procedures began Wednesday between Stanford University representatives and Santa Clara County officials.

In a joint statement today, County Executive Howard W. Campen, and Dr. Thomas Gonda, associate dean and acting director of Stanford University Hospital, said the meeting was intended to discuss suggested procedures to be followed in certain kinds of transplants as they involve the coroner's office.

In addition to Campen and Dr. Gonda, taking part in the discussions were Dr. John Houser, county medical examiner-coroner, William Siegel, County Counsel's office, Robert M. Brown, general legal council of the University, and other representatives of the Medical School.

Transplant #3 8-22-68

Stanford University surgeons have began their third heart transplant operation at 9:30 p.m. Thursday night.

The four and a half hour operation is expected to be completed at 2 a.m. PDT when further details will be disclosed.

The surgical team is headed by Dr. Norman E. Shumway, professor of surgery, who performed Stanford's two earlier heart transplant operations.

Condition reports are not expected until 10 a.m. Friday.

###

Drake / Smith

Aug 23, 1968

(2)

III

Surgeons at Stanford University Hospital Thursday night transplanted the heart of a Marine coporal into the chest of Leonard Drake, a 42-year-old retired postal clerk from Eugene, Oregon.

The donor, Cpl. Larry B. Smith, 20, of Stockton, California, suffered irreversible brain damage in an automobile accident August 14, at Stockton.

He was on leave from Camp Pendleton, visiting his parents Mr. and Mrs. Robert A. Smith of 2557 Bacon Street, Stockton. He was scheduled to leave for Vietnam following his leave.

Drake suffered heart disease for the past 12 years. He had retired from the post office job because of ill health and for the past year and a half had worked as bailiff for the Lane County District Court in Eugene.

Prior to his referral to Stanford, Drake had been under the care of a Eugene cardiologist and had been treated at the University of Oregon Medical School.

Mrs. Drake said Oregon doctors had told him a transplant was the only thing that could save his life and Drake had clung to this hope.

Since his transfer to Stanford in June he has remained under close medical supervision awaiting a suitable donor.

Corporal Smith is the youngest of 12 children of Mr. and Mrs. Smith, eight of whom are living. He attended Franklin High School at Stockton and he enlisted in the U.S. Marine Corps in May, 1966.

His parents said Smith volunteered three times to go to Vietnam. "Offering his heart to save the life of another person is something he would be proud of," said Mr. and Mrs. Smith. It was Smith's oldest brother, Gene, who suggested Larry's "strong heart be donated to give someone else a chance to live."

The Drakes have two children, Vicky, 11, and Jimmy, 10.

###

August 23, 1968

3 A

III

Mr. Drake, Stanford's third heart transplant recipient, is in satisfactory condition this morning.

His blood pressure and respiration are normal.

The patient is alert, awake, and was visited by his wife early this morning--about seven hours after the operation.

The patient is given breathing therapy to keep his lungs in full use--a normal procedure following such major surgery. (There is no tracheotomy as was in the case of previous heart transplant patients who had serious lung complications).

We have been asked to compare Mr. Drake's case with previous heart transplant recipients at Stanford.

Mr. Drake's coronary artery disease, which necessitated the transplant, was more severe than the heart condition of the previous patients. But his liver and lungs are in good condition.

Another question was if there was any difference in surgical technique. Dr. Shumway used the same techniques that he developed with his associates at Stanford University School of Medicine.

Stanford University surgeons also performed two kidney transplants from the body of the same donor. The patients' conditions are satisfactory.

###

III

(3b)

8/23/68

Statement on donor

The patient was transferred to Stanford University Hospital at 5 p.m. Thursday when those concerned with his care concluded that he had suffered permanent brain death or irreversible coma.

The criteria include irreversible brain damage, lack of spontaneous breathing, and absence or reflexes and other neurological signs that confirm the brain destruction. The donor selection and death pronouncement was made by an independent group of physicians not associated with the heart transplant team.

III

Mr. Drake is described as steadily improving this morning and doctors are satisfied with his progress.

His blood pressure and pulse remain normal. Mr. Drake has been sitting on the side of his bed. He is on a liquid diet.

Mrs. Drake visited her husband last night and this morning. She says that her husband has inquired about members of the Drake family in Eugene. Mrs. Drake said that her husband "looks good and is very confident." She is keeping him informed on the many get well wishes he has received from across the country.

August 25, 1968

(5)

III

Mr. Drake, Stanford's heart transplant recipient, continues to progress satisfactorily today, three days after the operation. His blood pressure, pulse, and cardiac output are normal.

The patient was out of bed this morning. He sat in a chair for a breakfast of solid foods. Doctors report that he asked for and received a second helping of warm cereal.

Mrs. Drake visited her husband again last night and this morning. She said that her husband is very anxious to have their two children fly to Stanford from Eugene as soon as they can see him. "The children are very excited about the trip," she said.

STANFORD - - When three-year-old Damian Pickering of Berkeley, California, was admitted to Stanford University Medical Center a few months ago his case appeared anything but hopeful.

His right eye was afflicted by retinoblastoma, a lethal tumor which is estimated to affect 1 in 30,000 children of his age in the United States.

This was Damian's second encounter with eye cancer. When he was eleven months-old his mother, Mrs. Michael Pickering, noticed a tiny white spot in the pupil of his left eye. She took the boy to a San Francisco ophthalmologist who diagnosed retinoblastoma. Because the tumor was too advanced to be treated with radiation, Damian's eye had to be removed to save his life.

The doctor also noticed another tiny tumor in the remaining eye, and referred Damian to Stanford for radiation treatment.

Radiotherapy has been used successfully at Stanford in the past 10 years for treating patients with retinoblastoma. Nine out of 10 patients respond well to treatment, said Dr. Frank C. Winter, clinical associate professor of surgery at Stanford University School of Medicine and Palo Alto practicing ophthalmologist.

At this point, it seemed as though Damian would recover normally. But in spite of receiving all the radiation his tiny eye could tolerate, the tumor's growth continued. By last February Dr. Winter and his associates feared they might not be able to save Damian's eye. Soon they would be battling to save the boy's life.

Yet today Damian Pickering is healthy. For thanks to an exciting new medical tool called cryosurgery, doctors were able to preserve his remaining eyesight and pull him back from the brink of death.

Cryosurgery is a method of treating body tissues particularly sensitive to extreme low temperatures (minus 100 to 140 degrees centigrade). Originally developed for highly sensitive brain surgery, the technique was applied for the first time in treatment of eye tumors by Dr. Harvey Lincoff of Cornell University. Damian is believed to be the first eye patient on the west coast on whom the method was used.

Although only about 10 retinoblastoma patients in the U.S. have been treated by the new approach, with varying degrees of success, Dr. Winter is optimistic about cryosurgery's future in the treatment of certain eye tumors.

"There is a significant number of patients who do not respond to radiation treatment," he said. "The only other life-saving approach now available is removal of the eye. Cryosurgery offers a third alternative in both saving lives and preserving eyesight."

-more-

In cryosurgery, tissues are frozen by liquid nitrogen which circulates through a miniscule probe made of platinum or other temperature conductive material.

When the probe tip touches the desired spot on the eye, ice crystals form inside the tumor cells. As they expand, the crystals begin to act like tiny sharp razor blades on tumor cell walls. By repeated freezing and thawing, tumor cells are lacerated and destroyed.

"Damian's treatment required six applications in one day under general anesthesia," Dr. Winter explained. "The tumor shrunk down to about one-third of its original size. By the time of his last treatment in June, the tumor had disappeared completely."

Unlike radiation treatment which is limited by the body's ability to absorb a certain amount of X-rays at a given time, cryosurgery can be used repeatedly without loss of effectiveness, Dr. Winter said.

Dr. Winter is now working with engineers at Union Carbide to develop a special probe suited for eye tumors. Such a tool, he believes, would greatly increase the effectiveness of the new treatment.

Retinoblastoma is a rare but life-threatening tumor of childhood. Two thirds of the cases appear before the end of the third year; rare cases have been reported at almost every age. It affects both eyes in about 30 per cent of the cases.

There is evidence the disease in inherited. Persons who have been cured of retinoblastoma are told they will have children with a 50 per cent chance of having the disease. Retinoblastoma usually develops inside the pupil of the eye. Growth involves development of many smaller tumors which gradually fill the eye and extend through the optic nerve to the brain.

Retinoblastoma usually remains unnoticed, said Dr. Winter, until it has advanced far enough to produce a white pupil. He recommends that parents who notice such a development report it promptly to their doctor.

FOR IMMEDIATE RELEASE

STANFORD--"A Lot of People Who Think for a Living Think the Next President Should Be Humphrey," read the bold headline of a full-page advertisement in the Aug. 4 issue of the New York Times. It was followed by a list of college and university faculty members endorsing the vice president.

One of the supposed supporters of Hubert Humphrey listed in the adverstisement was Dr. Felix Bloch, Max H. Stein Professor of Physics at Stanford University. Prof. Bloch, a Nobel laureate, has and continues to support the candidacy of Senator Eugene McCarthy.

Another alleged endorser of Humphrey was a Max H. Stein of Stanford University. The late Max H. Stein, who endowed the professorial chair held by Prof. Bloch, was a Southern California philanthropist who died in 1958.

Prof. Bloch, who has been deluged with questions as to why he seems to have changed horses in the middle of the stream, points out that this is certainly not the case.

"I state emphatically that I remain among the Scientists for McCarthy whom I greatly admire for his fearless approach to our foreign policy," he wrote in a letter to the Editor of the New York Times.

On July 1 Prof. Bloch received a telegram from the National Headquarters of "Citizens for Humphrey" in Washington, D. C., which asked him to join as a founding member of Scientists and Engineers for Humphrey. The telegram was signed by Robert Short, co-chairman of the group.

Prof. Bloch immediately wired Short that "Humphrey's record shows strong backing of U.S. involvement in Vietnam which did great harm to the country including its scientific development. Cannot support his candidacy unless he clearly commits himself to the change in foreign policy advocated by McCarthy."

Yet on Aug. 1, Prof. Bloch was advised by Robert P. Parker, executive director of "Citizens for Humphrey" that his name would appear as an endorsement of Humphrey in the New York Times. Prof. Bloch immediately called Parker and received due apologies and Parker's promise that all would be done to correct their mistake.

"I can only assume that it was too late to delete my name from the advertisement which appeared," he says.

A postgraduate course in operating room nursing will begin October 14 at Stanford University Hospital.

This will be the second time the course has been offered by the Hospital. Three registered nurses enrolled in the first session will complete their training in mid-August. They are Sandra Juracich, R.N., a graduate of the College of San Mateo School of Nursing in San Mateo, Calif.; Dolores Torrez, R.N., Texas Western University and Hotel Dien School of Nursing in El Paso, Tex.; and Ruth Barron, R.N., University of Wisconsin and St. Mary's Hospital School of Nursing in Madison, Wis.

Aimed at giving qualified R.N.'s a basic background in operating room procedures, the eight-month course includes instruction by experienced operating room nurses and lectures by surgeons and anesthesiologists, both community physicians and faculty members of the Stanford University School of Medicine.

Instruction stressing asepsis, anatomy, physiology and related subjects, in addition to practical aspects of operating room nursing, will cover eight hours a day, five days a week.

To give each participant individual attention, the course is limited to four registered nurses who will be selected on the basis of educational background and working experience, following a personal interview. The Hospital will pay a stipend to each nurse accepted for the program.

Interested applicants should contact Mrs. Ludmila Davis, R.N., director of Operating Rooms, in Room C-205A at Stanford University Hospital, Stanford, California 94305.

"Operating room nursing has become a highly technical field which demands specialized training," Mrs. Davis said. "New surgical procedures require skills that are not taught in the average professional school of nursing. We believe that post-graduate training courses are essential to avoid a shortage of qualified operating room nurses."

Robert G. Lindee has been promoted to associate dean for administration of the Stanford University School of Medicine. He will also continue to be assistant to the vice-president for medical affairs of the University.

The announcement was made by Dr. Robert J. Glaser, acting Stanford University president.

For the past three years, Lindee has been assistant dean for administration and assistant to the vice-president for medical affairs at the School of Medicine. He has been active on the California Committee on Regional Medical Programs and was also on leave to Washington D.C. where he served as a consultant to the director of the Division of Regional Medical Programs at the National Institutes of Health. He also serves as administrative consultant to various NIH health councils, and is a member of the California Ad Hoc Committee on Teaching and County Hospitals.

Prior to coming to Stanford in 1965, Lindee was associated for two years with Dr. Glaser when he was president of Affiliated Hospitals at Harvard Medical School. From 1959 to 1963, he served as an executive assistant to the vice-president for medical affairs and dean of the University of Colorado Medical School in Denver.

He holds bachelor of arts degrees in psychology and in school administration from the University of Colorado in Boulder. In 1952, he became assistant personnel director at the University of Colorado Medical Center and served in that capacity until 1959, with the exception of two years' leave for military duty.

STANFORD--Two years ago the life of Mrs. Marie Ooton of Mountain View was saved by a kidney transplant at Stanford University Hospital.

This summer she again entered the hospital but for a more joyous occasion--the birth of a six pound son, Shannon, on July 8.

At the time of the kidney transplant, Stanford doctors had cautioned Mrs. Ooton and her husband, Tom, a teamster with a Palo Alto construction and excavation firm, against having any more children. It was the pregnancy of their older son, Timothy, which had aggravated Mrs. Ooton's kidney failure, eventually resulting in the need for a transplant.

When Mrs. Ooton discovered she was pregnant again, physicians warned her that the pregnancy might possibly endanger her own life. After careful thought and deliberation with her doctors and her husband, Mrs. Ooton decided to have her baby.

"When I hold Shannon in my arms and care for him each day, I know I made the right decision," Mrs. Ooton says. She describes the pregnancy as "extremely easy and uneventful."

Throughout her pregnancy, Mrs. Ooton, a registered nurse and former employee of Stanford University Medical Center, remained under the constant and watchful eye of Stanford obstetricians.

The incidence of successful pregnancy for cases like Mrs. Ooton's is quite rare. While there have been reportings of full-term pregnancies in women who received a transplanted kidney from an identical twin, there are believed to be only three other cases in women who received kidneys from donors other than identical twins.

Donor of Mrs. Ooton's kidney was her older brother, Dr. Philip Avet, chief resident in pathology at Charity Hospital in New Orleans. The operation was performed Nov. 7, 1966, and Dr. Avet returned to New Orleans a week later.

-more-

At the time of the transplant Dr. Avet said he had had no difficulty in deciding to donate one of his kidneys to his sister. "When I was called to come to Palo Alto, my sister was dying," he said. "I've always felt close to Marie, and I believed I owed her a fighting chance."

Mrs. Ooton visited her brother last winter but did not tell him she was expecting another child. "Knowing the dangers involved, he would have been extremely worried," she says. Dr. Avet was informed that he had a new nephew on the day that Shannon was born.

Today both mother and child are doing well. Mrs. Ooton's transplanted kidney continues to function well as it did throughout her pregnancy.

As a kidney transplant patient, Mrs. Ooton still remains in close contact with Stanford physicians. She continues to be given small amounts of immunosuppressive drugs to counteract any rejection of her transplanted organ.

###

Mailed September 18, 1968.

Mrs. Marie Ooton of Mountain View, who received a kidney transplant two years ago at Stanford University Hospital, was cautioned at that time against having any more children. When she discovered she was pregnant again, knowing that the pregnancy might endanger her own life, she decided to have her baby. On July 8, 1968, Mrs. Ooton gave birth to a healthy six pound son, Shannon. Both mother and child are doing well. The incidence of successful pregnancy in women with transplanted kidneys is quite rare.

STANFORD--Fourteen scientists from 12 countries have gathered at Stanford University School of Medicine for an intensive course in the use of computers for biomedical research.

Utilizing the facilities of Stanford's Advanced Computer for Medical Research (ACME), the international trainees are learning the art and language of programming, developing new techniques in computer use, and evaluating the various possibilities for application of computers for research in their respective countries.

The two-week training course is sponsored by the United Nations Educational, Scientific and Cultural Organization (UNESCO) and one of its divisions, the International Cell Research Organization. Scientists attending the course are from South Korea, France, Spain, England, Israel, Norway, Austria, Australia, Czechoslovakia, Nigeria, Italy, and Thailand.

Coordinating the program for the visiting trainees in Dr. Joshua Lederberg, Stanford Nobel Prize-winning geneticist who was instrumental in the conception and development of the ACME project.

"The increasing sophistication of medical research, both in the United States and abroad, has made it necessary to be able to both record and retrieve large volumes of information for statistical and diagnostic studies," Gio Wiederhold, who directs the ACME project at the Medical School, points out. "Until recently the capability to provide this information has lagged considerably in comparison to demand."

ACME, with financial support from the National Institutes of Health and the Josiah Macy Jr. Foundation of New York, was developed to meet this demand. Now utilized on a regular basis by almost 50 per cent of the faculty and staff of the Medical School, the ACME system has important application not only for medical research but also for the actual care of patients and the development of new concepts in health care systems.

- more -

Among those medical tasks being tackled by computers at Stanford are:

--Studying the structure of molecules which define our genetic makeup.

--Monitoring patients during surgery to warn of possible cardiac failure.

--Analyzing with mathematical accuracy complex data from electrocardiograms.

--Matching donors and recipients for kidney transplants.

--Studying what happens when a person breathes--rate and amount of air intake, changes in lung and rib cage pressure.

--Plotting the pathway of single nerve cell discharges to the brain in both normal and epileptic subjects.

--Predicting effects of smog and other polluted environments on human cells and function.

The system, which began routine operation in January, 1967, utilized IBM 360-50 and IBM 1800 computers plus ancillary equipment. Data flows to and from the main unit through 60 terminals located throughout the Medical School and on the main Stanford Campus nearby.

"The presence of these terminals enables direct connection between the laboratory instrumentation and the computer and allows collection and analysis of experimental results from many different laboratories," Wiederhold says. "It also makes it possible for the investigator to have full control over the instructions and data fed to the computer and over the procedures executed by the system."

The ACME system also allows for "real-time processing," enabling the analysis of data during the actual time of experiments. Another concept built into the system is that of "timesharing" so that the attention and memory of the system can be divided according to the varying needs and problems of many researchers at the same time.

"The ACME system can fulfill the requests of a dozen users within one second," according to Wiederhold.

Transplant #5 Asche/Anonymous

A housewife from Los Altos Hills became the fifth heart transplant patient today at Stanford University Hospital.

The recipient is Mrs. Virginia Asche, 48, who received a new heart in a 4½ hour operation by a team of surgeons headed by Dr. Norman E. Shumway, professor and head of the division of cardiovascular surgery at Stanford University School of Medicine.

Mrs. Asche is the first woman to undergo heart transplant surgery at Stanford. Her condition is listed as satisfactory.

The new heart came from an anonymous donor who suffered irreversible brain damage and died at Stanford University Hospital this morning.

Mrs. Asche, whose husband, Charles, is a financial and real estate consultant, has had several heart attacks and has suffered heart failure for the past two years.

Mr. Asche noted this morning that the development of heart transplantation "has given my wife a chance to live." The Asches have lived in Los Altos Hills for the past six years.

Also at Stanford two other heart transplant patients continue to make steady progress. Leonard Drake, 42, from Eugene, Ore., received a new heart on Aug. 22 and Robert O. McKee, 51, a Palo Alto engineer, underwent heart transplant surgery on Aug. 31.

####

September 10, 1968

Mrs. Virginia Asche, the first woman to receive a heart transplant at Stanford University Hospital, continues to be in satisfactory condition this morning.

Mrs. Asche is awake and alert. Her blood pressure and pulse are normal. She is on a liquid diet.

Mr. Asche visited his wife last evening.

####

Sept 11, 1968

Mrs. Virginia Asche continues to make steady progress today at Stanford University Hospital following her heart transplant operation Monday. She had breadfast this morning seated in a chair in her room. Mr. Asche visits his wife frequently.

Robert O. McKee who received a new heart at Stanford on Aug. 31, is being treated for what physicians describe as a "rejection episode." He is being given increased amounts of immunosuppressive drugs to counteract the bodies natural tendency to reject foreign tissue.

Doctors report that Mckee spent a comfortable night.

Leonard Drake continues to make steady progress. He received a transplanted heart on Aug. 22.

####

September 12, 1968

Robert O. McKee continues to be treated for rejection of his transplanted heart and is reported slightly improved today at Stanford University Hospital. He remains in satisfactory condition. McKee is not confined to his bed and was up and about today following breakfast.

Mrs. Virginia Asche is described as making steady progress today. She is also out of bed for brief periods and is on a normal diet.

Leonard Drake continues to make steady progress each day. He has been moved from the Intensive Care Unit to a private room.

####

Virginia Asche
Dead January 14, 1969

Virginia Asche, the 48-year-old Los Altos Hills housewife who underwent a heart transplant operation last September 9, died today at Stanford University Medical Center.

Mrs. Asche died of hepatitus after re-entering the hospital a week ago.

She was the first woman and the fifth person to undergo heart transplant surgery at Stanford.

The wife of Charles Asche, Palo Alto real estate broker, Mrs. Asche had sufficiently recovered from the transplant operation to return to her home on October 12 and was leading what was described as a normal life until she was stricken with hepatitis.

In addition to her husband, Mrs. Asche is survived by her mother.

Ten heart transplant operations have been performed at Stanford University Medical Center by a team headed by Dr. Norman E. Shumway.

Two of these were performed on the same patient, and of the nine individuals receiving new hearts at Stanford, only three survive.

Science Writers: The following story is based on a paper by Dr. Norman E. Shumway prepared for presentation at the Second International Congress of the Transplantation Society in New York City.

FOR AM RELEASE SUNDAY, SEPTEMBER 8, 1968

NEW YORK -- Patients with long-standing heart failure whose neighboring organs have undergone significant adaptive changes are high risk candidates for heart transplantation, Dr. Norman E. Shumway, Stanford's pioneering cardiovascular surgeon, said today.

In his remarks, prepared for delivery Sunday at the Second International Congress of the Transplantation Society in New York, Dr. Shumway compared the cases of Mike Kasperak, 54, and Joseph Rizor, 40, who died following heart transplants at Stanford earlier this year, to two recent heart transplant patients who are living.

Co-authors of the report are members of Dr. Shumway's heart transplant team, Drs. Edward Stinson, and Eugene Dong, Jr.

"Death of our first heart transplant recipient appeared to substantiate the theory that transplantation of the heart offers little to the patient whose death is imminent from the effects of chronic heart failure on other organs," Dr. Shumway said. "The history of our second case almost certainly converts this theory to fact."

Kasperak died 15 days after the operation from what Dr. Shumway termed "a galaxy of complications" involving the lungs, liver, and kidneys. Rizor died three and a half days after receiving a new heart because his sick lungs were unable to oxygenate his blood.

Dr. Shumway said the second case illustrates the need for transplantation of the heart and one or both lungs. He emphasized that "patients with long-standing cardiac failure whose neighboring organ systems have undergone significant adaptive changes are high risk candidates for transplantation of the heart."

- more -

"The third and fourth heart transplant recipients have done remarkably well in the early postoperative phases," Dr. Shumway reported.

Stanford's newest transplant patients, Leonard Drake, a 42-year-old retired postal clerk from Eugene, Ore., and Robert O. McKee, a 51-year-old Palo Alto engineer, are doing well following heart transplant operations 18 and 9 days ago respectively.

Although both patients had suffered from acute coronary artery disease requiring transplants, neither had irreversible damage in such important organs as the lungs and liver, Dr. Shumway said. Patients in acute heart failure are suitable candidates for transplantation because the secondary effect on other organs is completely reversible.

Drake is up walking, eating well, and requires no pain medication in marked contrast to his condition before the operation. McKee is improving normally.

"There have been no clinical or laboratory signs of rejection," Dr. Shumway said. Both patients, however, are receiving small daily doses of immunosuppresive drugs including antilymphocyte globulin.

Dr. Shumway said that neither of the first and second Stanford heart transplant patients showed any clinical evidence of rejection. He added, however, that testing of tissue compatibility prior to the operation and the diagnosis of early rejection after the operation "remain crucial areas for further clinical and laboratory investigation."

He predicted that eventually "heart transplantation should achieve the same clinical status as kidney and liver transplants."

Dr. Shumway's work is supported by grants from the National Institutes of Health.

STANFORD -- Interferon, a natural antiviral substance produced by the cells and considered to have potential value in the control of virus disease in man, has been found to protect cells against toxoplasmosis.

The finding, reported by researchers from Stanford University School of Medicine, suggests a role for interferon with organisms higher than viruses including those responsible for such diseases as malaria and sleeping sickness.

Viruses such as those causing the flu, polio or the common cold are simpler than the parasite which causes toxoplasmosis. Toxoplasma, being protozoa, are much larger and more complicated than viruses and have apparatus capable of self-reproduction in their structure. Certain protozoa even reproduce themselves outside of cells. Viruses can only reproduce themselves inside body cells.

Toxoplasmosis in the newborn can be a serious illness, killing some if its victims in infancy, blinding, crippling, or producing deafness or mental retardation in others. The parasite, evidently, is extremely common throughout the world. Large numbers of people appear to have antibodies against it, indicating they have been infected at least once.

The discovery of interferon's power against toxoplasma and possibly more complex organisms was reported in a recent issue of SCIENCE, the journal of the American Association for the Advancement of Science. The studies were carried out by Dr. Jack S. Remington, assistant professor of medicine at Stanford and director of the Division of Infectious Disease at Palo Alto Medical Research Foundation, in collaboration with Dr. Thomas C. Merigan, associate professor and head of the Division of Infectious Diseases at the medical school.

Their work was supported by a grant from the National Institutes of Health.

- more -

Independent confirmation of the Stanford investigators' report on the infection-controlling range of interferon has come from New York University researchers. They found agents that promote interferon production can prevent or delay fatal malaria infection in mice. The New York University research was conducted by Dr. Rene I. Jahile and his associates.

The Stanford researchers treated chick and mouse cells with interferon and exposed the cells to toxoplasma germs. They found the cells "were significantly protected from destruction by the toxoplasma."

Interferon is a protein which is normally produced by the cells in the body to limit the spread of virus infection. Ever since its discovery by Drs. Alick Isaacs and Jean Lindermann at the National Institute of Medical Research in London in 1957, interferon has been considered to have potential value in the control of virus disease in man, ranging from the most deadly virus infections to the common cold, for which no vaccines or chemical weapons are presently available.

Researchers in several medical centers throughout the world have been working to develop drugs which stimulate interferon production in the cells to protect populations from infection during epidemics.

STANFORD -- Dr. Jan Klein of the Czechoslovak Academy of Sciences Institute of Experimental Biology in Prague is visiting Stanford University as a research associate in the Department of Genetics from August 30 to January 31, 1969.

The 32-year-old scientist will work with Dr. Leonard Herzenberg, professor of genetics at Stanford University School of Medicine. Dr. Klein, a well-known authority in the field of transplantation genetics, has worked at Stanford before from February 1, 1966 to March 7, 1967.

Dr. Klein arrived in the United States on August 30 after attending the 12th International congress of Genetics in Tokyo, Japan. Dr. Klein's visit was arranged seven months ago. He will be at the University under Stanford's exchange visitors program.

Following his visit at Stanford, Dr. Klein will go to the University of Michigan for further research work before returning to Prague.

STANFORD--A critically important measure, which will permit nonprofit California hospitals to keep pace with the demands placed upon them by the state's burgeoning growth, has been endorsed by a local group of leading citizens.

Dr. Russel V. Lee, founder of the Palo Alto Medical Clinic; Stanford University Hospital board members James E. O'Brien, Mrs. Edward H. Heller, Robert H. Klein, John M. Santana, Jr., and Raymond Rohrs; City Councilwoman Frances Dias, and Drs. James I. Ball, Walter L. Arons, and Edward A. Barthold are members of the local group of Californians for Modern Hospitals urging passage of Proposition 5.

Placed on the November ballot by a nearly unanimous vote of the State Legislature, the measure would amend the State Constitution to permit the state to guarantee loans made by banks and other financial institutions to nonprofit and public agencies for the construction of hospital facilities.

The plan would work like existing federal and state home loan programs. As long as the hospital repays its loan on time, the state will contribute nothing. But if the hospital is unable to meet payments, the state will pay off the loan.

Hospitals, according to the California Hospital Association, find it difficult to obtain private financing at the present time because few banks are willing to foreclose on a hospital. Therefore, lending institutions are unwilling to accept hospital property as security.

Passage of the measure, authored by State Sen. Stephen P. Teale, would permit the state to substitute the insured loan program for the direct grants it has been making to match federal Hill-Burton contributions to hospital construction programs.

State appropriations for matching hospital funds have run from $15 to $20 million a year. But the Hill-Burton Act may expire next year and Gov. Ronald Reagan has said the state will not be able to make direct grants to hospital construction after this fiscal year.

The local backers of Proposition 5 say State Department of Public Health figures indicate California now faces a shortage of 21,523 modern hospital beds. The problem will become more acute as the nation's most populous state continues to grow.

They pointed out that North Santa Clara County has faced a serious shortage of hospital beds for several years. Stanford University Hospital facilities, which serve both the faculty and community physicians, will be falling seriously behind community needs as construction costs soar and medical technology brings more and more citizens in the mainstream of health care.

"We urge a 'Yes' vote on Proposition 5 as a measure critical to the effectiveness of the community's health care programs," the committee said.

Science Writers: Dr. Kornberg's remarks will be made in connection with his acceptance of the 1968 Borden Award of the Association of American Medical Colleges. It will be presented at the awards dinner Saturday, November 2, as part of the Association's annual meeting in the Shamrock Hilton Hotel in Houston.

FOR RELEASE SUNDAY, NOVEMBER 3, 1968

HOUSTON, TEXAS--Sharp cutbacks in federal support threaten the very foundation of American research enterprise, the nation's medical educators were told here Saturday.

The warning was issued by Dr. Arthur Kornberg, Stanford University's Nobel Prize-winning biochemist, as he accepted the 1968 Borden Award of the Association of American Medical Colleges "for outstanding research in medicine."

"Research is the lifeline of medicine," Dr. Kornberg said. "It is an enterprise requiring men, money and momentum. Don't believe that it resembles a steel furnace that can be banked temporarily and then fired up when needed."

"The miracle of the American research enterprise of the last two decades can vanish as mysteriously as it arose. Please don't let it happen," Dr. Kornberg added.

A generation ago, when research support was meager, most research workers had a deep drive to do research. Some did great things. Some didn't, Dr. Kornberg related. In recent years the nation has supported more than ten times as many research workers as a generation ago. But some of their contributions are outstanding and most of what they do adds to the foundation and techniques of modern science.

"I believe the absolutely phenomenal advances in basic medical sciences in the past two decades are not the achievements of a few geniuses but the massive effort of a large number of people. These people were judged by their peers to be well-trained and competent and were awarded research grants," he said.

But research support has been cut back, Dr. Kornberg said, and at this moment administrators and research workers all over the country are arguing among themselves how to apportion this cut.

Should the cut be apportioned evenly among grantees or should ratings be assigned, eliminating researchers progressively from the bottom of such list? he asked.

Dr. Kornberg stressed that to follow either course "is a disaster for the progress of science. To curtail the efforts of highly gifted, productive groups at the peak of their creativity is unconscionable."

He doubted, he said, that there is a crystal ball that could help a dean, a department head, or a committee of experts to pinpoint the "pedestrian" work that can be dispensed with.

-more-

"Next month three biochemists will receive the Nobel Prize in medicine for the extraordinary research that disclosed the genetic code," Dr. Kornberg said. "Had there been a cut of 40 per cent of a grantee list at the time their research was starting 10, 15, 20 years ago, I doubt that all of their projects would have survived it."

Dr. Kornberg's remarks were made at the award banquet at the Shamrock Hilton Hotel as part of the Association's 79th annual meeting.

In addition to a medal, the Borden Award carries a prize of $1,000.

In 1959, Dr. Kornberg was named a Nobel Laureate in recognition of his discovery of the enzyme DNA polymerase, a discovery that made possible further probing of the mechanisms of nucleic acid biochemistry. He and his associates only recently announced the synthesis of infective viral DNA (deoxyribonucleic acid).

"It is for this work especially," read the award citation "that he is receiving the Borden Award--an accomplishment that has been termed a major event in the Twentieth Century and one of enormous significance to research in biochemical genetics."

The Borden Award was established in 1947 by the Borden Company Foundation. It is presented in recognition of outstanding clinical or laboratory research by a faculty member of a medical school which is a member of the Association of American Medical Colleges.

STANFORD--A new program for training workers from racial minorities as laboratory assistants and technicians has been inaugurated by the Stanford University School of Medicine.

The program, which will provide intensified training in laboratory procedures for four months, began in October with seven students from East Palo Alto, Palo Alto, Mountain View and Milpitas. The students' backgrounds range from 7 to 12 years of formal education.

Trainees enrolled in the program receive a salary during their training. For the first six weeks, they will be exposed to formal lectures, films and laboratory exercises. For the remainder of their training, the students will work in selected laboratories in the Medical School while attending classes one afternoon a week. After their training is over, the trainees will become regular employees at the Medical Center.

The new program is the brainchild of Moses A. Thomas, 30-year-old laboratory coordinator in the Department of Genetics of the Medical School. Thomas lives with his wife and three children in East Palo Alto. He is also past executive chairman of the East Palo Alto NAACP branch.

Thomas found that most beginning laboratory technicians with a college degree in biology and no experience in a research laboratory are at once overtrained and undertrained.

"They are overtrained," he said, "in the sense that they have been given a great deal of theoretical knowledge out of context and they are generally not able to apply very much of it to the specific research problems of the laboratory. They are undertrained in that they have not been rigorously schooled in handling even the simplest laboratory tools such as pipets, and modern balances."

He concluded that a person with less theoretical experience, but well grounded in laboratory techniques would be a desirable laboratory assistant, especially in laboratories which require several assistants.

Thomas had plans for a more ambitious program for minorities which would accommodate 20 instead of seven students. "Unfortunately," he explained, "it had to be limited because of recent cuts in federal research support which have affected the University budget. I worked very hard in getting this program implemented, along with some faculty and staff members and the support of the dean."

Dr. Thomas Merigan, associate professor and head of the Division of Infectious Diseases, is chairman of the faculty committee for the program.

-more-

"We are taking minorities presently employed in an unskilled field and giving them a chance to function in a different atmosphere," Thomas said. One student, for example, was a lab dishwasher, another was employed in the hospital food service.

Cliff Jenkins, senior research assistant in the Department of Psychiatry, has volunteered to teach students methods of measurement in laboratories.

"He is a very patient and understanding instructor and has done a remarkable job in teaching," Thomas said.

Students are taught how to handle data, read and construct graphs, and to utilize common mathematical equations. They are getting a thorough knowledge of exponential notation along with a reasonable understanding of the slide rule. Other subjects include instruction in international atomic weight charts, elements, symbols, atomic numbers, and teaching a basic understanding of volume, distance, mass and the metric system.

Students are also acquiring practical experience in the use of the chemical balance and a variety of volumetric techniques. Special emphasis is placed on accuracy and critical analyses of data. The students are preparing solutions and buffers, and some time is spent learning basic skills useful in chemical analysis, including procedures of radioactive assay.

Thomas described the first three weeks of the program as gratifying. "We are now beginning elementary laboratory experiments with great success," he said.

Students in the program are Mrs. Gladys Braud, Mrs. Johnnye Jennings, and Mrs. Lois Johnson, all of East Palo Alto; Mrs. Jackie Faison and Eddie Padilla of Mountain View; Lyman Whitman of Palo Alto; and John Miller of Milpitas.

###

Mailed October 28, 1968.

STANFORD--Stanford University Medical Center today announced a major drive to increase the number of workers from racial minorities in the School of Medicine and Hospital.

The program calls for steps to improve representation of minorities in the Center, and for creation of on-the-job training programs and opportunities for promotion and placement.

The program was announced by Dr. Thomas A. Gonda, associate dean of the School of Medicine and acting director of Stanford University Hospital.

Also announced was the appointment of two minority relations representatives, Moses A. Thomas, 30, and William Stone, 29, both of East Palo Alto.

Thomas, a laboratory coordinator in the Department of Genetics, will be responsible for medical school programs. Stone will be responsible for Hospital programs. They will explore within their respective areas where training programs for minority employees might be initiated and they will work with personnel officers to see that all new positions are advertised.

A committee on minority employment at the Medical Center has also been formed to review proposals and to assist and advise the minority relations representatives as well as the administration in setting up needed programs. It will also function as a grievance committee for minorities. Harry H. Ball of Milpitas, mail room supervisor at the Hospital, is committee chairman.

Thomas directs a program now in operation at the Medical School for training minority workers as laboratory assistants. The six-week intensive course is in its second week with seven students. Thomas attended Southern University in Baton Rouge, La., and the College of San Mateo. He is also past executive chairman of East Palo Alto NAACP branch.

Stone attended the College of San Mateo, Foothill and San Jose State Colleges. He also worked as a teaching assistant at Green Oaks Junior High at East Palo Alto. Since leaving this job he returned to Foothill and joined the Stanford hospital as assistant mail room supervisor.

-more-

Ball joined the Hospital following his retirement from the U.S. Postal Service in 1966 after 30 years of service. He was general delivery clerk at Stanford Branch Post Office. He attended the University of Iowa in Iowa City, and Howard University in Washington, D.C.

The new program for minorities incorporates proposals of the committee on minority employment and recommendations of a task force of hospital supervisory personnel. The groups met several times since August to develop recommendations for minority employment and training practices at the Hospital.

The committee has proposed that initial steps for promotion and placement of minorities be directed at hospital areas where on-the-job training can be accomplished. It suggested that three departments in the Hospital be given a priority for the project.

These departments would be picked on the basis of size and number of male workers they could accommodate. "Priority should be given to upgrading male or female workers who represent the bread winner," said the committee. "The need for immediate action dictates that we move in those areas which do not entail long-range planning."

Other proposals call for designation of training officers in Hospital departments and for review procedures of trainees' progress. Problems arising during an employee's training may be reviewed by the minority relations representative or by the minority relations committee.

The committee includes Alvin Anglin and James Boyd, housekeeping; Harry Ball and William Stone, mail room; James Cheatham, inhalation therapy; David Edwards, messenger service; Ray Scoggins, cast room; Moses Thomas, department of genetics; Robert Peterson, stores; Mel Barries, physical therapy; Mrs. Lovie Lewis, Hoover pavilion; and Mark Steward, department of pathology.

Ronald Bush was transferred Monday afternoon to Stanford University Hospital as a potential donor after Stanford physicians had been contacted by Oroville doctors. He was suffering from a gunshot wound in the head. Bush's parents had given permission for donating of their son's heart after they had been told nothing could be done to save his life.

Bush was admitted to the Hospital for tests and the Santa Clara County Medical Examiner Coroner's Office was notified as prescribed by present guidelines regarding transplantation. The Coroner's Office contacted Oroville officials. It was told that Bush's wound was self-inflicted. On the basis of this information, Santa Clara County Coroner's office cleared the case for tests and possible transplantation. No surgery, however, had been scheduled.

At 11 p.m. Monday, Butte County officials notified the Santa Clara County Coroner's office that a possible murder was involved in the fatal shooting of Bush. Tests were then halted at the request of the Coroner pending further investigation.

Bush died at the hospital Tuesday afternoon at 4:40 p.m. His body has been turned over to the Santa Clara County Coroner for an autopsy.

HEART TRANSPLANT #7

BULLETIN # 1

STANFORD — Carl P. Sheaffer, 54, of Winchester Bay, Oregon, became Stanford University Hospital's seventh heart transplant patient today.

Donor of the new heart was David Brewer, 20, son of Mr. and Mrs. John C. Brewer of Campbell, California. He died at 8 a.m. Saturday at the Stanford hospital of a gun shot wound in the head.

Brewer was transferred to Stanford from Santa Clara Valley Medical Center where he had been hospitalized since Friday ~~following an apparent suicide attempt at his home.~~

Sheaffer, the heart recipient, is a retired plumber and father of five children. He suffered from arteriosclerotic heart disease which progressed since his first heart attack in 1963. He retired in 1964 as a result of his illness.

The operation, which began at 9 a.m. was performed by a surgical team under the direction of Dr. Norman E. Shumway, professor and head of the Division of Cardiovascular Surgery.

Also at Stanford this morning, another surgical team transplanted one of Brewer's healthy kidneys in Martin L. Paduck, a 43-year-old retired army sergeant from Salinas, California. Paduck is the father of three children.

Both patients were reported in satisfactory condition after their operations.

Another heart transplant patient at Stanford was reported making satisfactory progress today. She is Mrs. Georgette Larson, 54-year-old San Jose housewife, who received a new heart October 5. Two other patients have left the hospital since they received new hearts August 31 and September 9. They are, however, required to report to the hospital daily for checkups.

Sheaffer's children are Mrs. Dorothy Jane Buffington of Los Angeles; Mrs. George Buffington and Carl F. Sheaffer Jr., of Franklintown, Pa.; and Ronald E. and William E. Sheaffer of Winchester Bay, Ore.

STANFORD--Heart transplant patient Robert O. McKee of Palo Alto expressed deep gratitude to members of the Stanford University Medical Center staff Friday as he prepared to go home.

McKee is the first Stanford heart transplant patient to be released from the hospital. He received a new heart on Aug. 31 in an operation performed by Dr. Norman Shumway, professor and head of the division of cardiovascular surgery at Stanford.

Donor of McKee's new heart was Dr. William Sample, 39, of Menlo Park. Dr. Sample was chief psychiatric social worker and acting director of the Children's Health Council in Palo Alto. He died of a massive brain hemorrhage.

"I feel very humble," McKee stated Friday afternoon as he said goodbye to doctors and nurses at Stanford. "It would take a poet to express my feelings and gratutude about what has happened to me in the last six weeks. Simply saying 'thank you' does not seem adequate."

McKee, a manufacturing methods engineer, said he hopes to return to work, although he has no specific plans at this time. A former supervisor for Beckman Instruments in Palo Alto, he had resigned last year because of his heart condition.

"I can breathe once more and I feel like living again," McKee said. "I want to return to society and participate as a useful and productive citizen. I realize that it is going to take effort on my part, but the desire is there."

"I also hope to prove that heart transplantation can return a man such as myself who was physically disabled by heart disease to a normal life again."

McKee will visit the hospital briefly several times a week for tests and checkups.

He has also requested that he not be contacted by members of the news media at this time.

STANFORD--Guidelines aimed at clearing legal obstacles regarding potential donors in life-saving heart transplant operations have been agreed upon by Santa Clara County officials and representatives of the Stanford University School of Medicine.

The guidelines clarify the circumstances under which hearts, kidneys, and other organs and human tissues may be donated for medical purposes from dead persons who legally are under the jurisdiction of the Medical Examiner-Coroner's office.

Agreement on the new procedures was announced today in a joint statement by Dr. John Hauser, Santa Clara County medical examiner-coroner, and Dr. Thomas A. Gonda, associate dean and acting director of the Stanford University Hospital.

"The guidelines are designed to assist in making cases where an autopsy is necessary--generally violent deaths--available as transplant donors. The guidelines could become a model for adoption throughout California," Drs. Hauser and Gonda said.

"Persons dying of violence or by unnatural means come immediately under the jurisdiction of the medical examiner-coroner at the time of death," the statement said. "Many such cases are medically ideal for use as transplant donors. The stringent time limits for the removal of organs immediately after death of the donor, however, ordinarily make it difficult for the medical examiner-coroner to make an adequate investigation as required by law."

The new guidelines include the following provisions:

--The medical examiner-coroner will be notified before death in all instances where cases legally under his jurisdiction are proposed as transplant donors.

--The medical examiner-coroner will make an investigation into the circumstances of the death to satisfy his legal responsibilities. Each case will be decided individually and will be released as a donor of specified organs..

--If the medical examiner-coroner believes that a case must not be used as a donor, the responsible physician will be notified and the body will not be disturbed, regardless of whether or not a consent of next of kin has been obtained.

The guidelines also provide that certain categories of violent deaths will not be used as transplant donors. These include known or suspected homicides, known industrial accidents, and cases with serious suspicion of poisoning.

Except for unusual circumstances the coroner will not allow use of victims of automobile and motorcycle accidents or apparent suicide in which more than one person is involved.

The guidelines require that death of the donor must be determined by a minimum of three physicians other than those on the transplant team, including--if available--the donor's personal physician.

In addition to Drs. Hauser and Gonda, those involved in the development of the guidelines included Robert M. Brown, general legal counsel of the University, Howard W. Campen, county executive, and William Siegel, county counsel's office.

STANFORD--Richard F. O'Brien, 47, has been appointed to a newly created position of Secretary of the Stanford University Medical Center.

His appointment was disclosed today by Acting University President Robert J. Glaser. Former director of development at Stanford, O'Brien has served as assistant to the president since July, 1967.

"In his new capacity, Mr. O'Brien will coordinate all fund raising for the two components of the Medical Center--the School of Medicine and the Stanford University Hospital and Clinics," Dr. Glaser said. "I am delighted that he will now direct his efforts toward helping us meet some of our pressing financial needs."

Dr. Glaser also announced that Peter E. Pratt, formerly director of Medical School development has assumed new responsibilities in the office of the General Secretary, staffing the University's special gifts committees on the East Coast. Mr. Pratt will continue, however, to direct the Medical School Annual Fund and to coordinate Medical School Alumni activities.

Stanford University, which recently acquired ownership of Palo Alto's interest in the former Palo Alto-Stanford Hospital, is contemplating a major expansion of its Medical Center in the near future. Planning efforts envision the development of additional facilities for the basic sciences, and a teaching hospital and ambulatory care center which will make feasible new approaches to patient care, teaching and research, and permit rigid control of costs.

O'Brien played a key role as director of Stanford's $100 million PACE campaign, which set a new high in capital gifts to an American university. From 1964 to 1967, he served as vice-president for planning and development at The University of Chicago where he planned and launched a $160 million capital campaign being successfully concluded this year.

Holder of two Stanford degrees (A.M. 1947, Ed.D. 1950), he has been associated with the University almost continuously from 1946 to 1964, both as a student and a staff member.

Starting as a resident counselor in student living units, he held several posts in the Dean of Students office and School of Education before being named associate general secretary of the University in 1954. He became director of development five years later.

A graduate of the University of California at Santa Barbara (A.B. 1943), he married the former Doris May Kirsten of Santa Barbara in 1943. They have three daughters: Mrs. Jon M. Cretarolo, Cynthia Ann, and Sally Jane.

STANFORD--Physicians at Stanford University Medical Center are now using computers to evaluate and diagnose heart disease and often to help in the evaluation of prospective heart transplant recipients.

This is the latest example of the use of computer technology in medical care, developed after two years of study and trial. Dr. Donald Harrison, associate professor of medicine and head of the division of cardiology at Stanford University School of Medicine, describes the use of computers as "an important tool which provides vital information for treating patients with heart disorders."

The facilities of the medical school's Advanced Computer for Medical Research are being used daily in the cardiac catheterization laboratory where detailed studies of heart function are performed.

In this, like other applications, information gathering and analysis is basic--and information processing is the computer's reason for existence. A computer is first of all a calculating machine of incredible speed. Its power to manipulate facts can be linked to memory units that give it access to vast amounts of data. But the computer's real value resides in its ability to carry out man's instructions--to make thousands of comparisons between incoming data and information in its memory and then to make predetermined choices based on those comparisons--all in a fraction of a second.

"Catheterization is carried out on all patients being considered for open heart surgery," Dr. Harrison cites as an example. "The procedure is instrumental in evaluating what the cardiac disorder is, the extent, location, and size of it, and how well the muscle of the patient's heart is functioning as a pump at the time of the study," he says. "It is also valuable postoperatively to insure that the heart malfunction has been corrected."

When a patient is catheterized, small, hollow tubing is painlessly inserted through the venous system of the arms or legs to the various chambers of the heart which are to be studied. The catheter takes blood samples and various pressure readings. By exacting mathematical calculations, physicians can determine if the heart's function and output of blood are normal, and if not, why not.

Before Stanford cardiologists began using a computer to analyze the catheterization data, it took often four to six hours to make the necessary calculations in evaluating a patient. Results of studies done on a patient early in the morning would not be available until late that day or even the next day.

-more-

"The computer enables us to have the catheterization material instantaneously," Dr. Harrison points out. "We can have the information analyzed and back in our hands while a procedure is still underway, thus making it possible for modifications to be made when necessary."

The computer can also analyze data which could not be calculated by hand because of the large number of data components. It has also proved to be more accurate in some cases than the calculations done in the traditional manner.

"We now have a more complete and efficient evaluation of our patients' heart function than we have had before," Dr. Harrison says.

The value of the computer in analysis will increase in the future. As data on the heart function of more and more patients are stored in the computer, physicians, when studying new patients, will automatically be able to compare the new information with that of previous patients with the same cardiac disorder.

Dr. Harrison and his associates, Walter Henry, a fifth-year medical student at Stanford, Dr. Robert Stenson, a postdoctoral fellow in cardiology, and Linda Crouse from the computer center, are exploring the possibility of making the programming techniques and facilities at Stanford available to other cardiologists. It would be possible, Dr. Harrison explains, for physicians throughout California to send their data over telephone lines to the Stanford computer center for rapid and accurate analysis.

###

Mailed October 9, 1968.

COMPUTER STUDIES HEART DISORDERS--Stanford cardiologists, Dr. Donald Harrison and Dr. Robert Stenson (in white coats) check data on patient's heart function being recorded for computer analysis at Stanford University Medical Center. A computer is being used routinely at Stanford to provide what Dr. Harrison describes as "a more comprehensive evaluation of heart disorders than has been possible before." Assisting Dr. Harrison and Dr. Stenson are Dr. Ralph Gianelly and Dr. John Hamilton.

STANFORD--The faculty senate of the Stanford University School of Medicine Saturday gave its unanimous approval to proposals for increasing minority student enrollment in the School of Medicine.

In a statement issued today, the faculty senate reiterated its concern over the problem of increasing minority student enrollment and noted that for the past six months, on the initiative of the dean and Medical School executive committee, faculty and students have been considering mechanisms for accomplishing this goal.

Dr. Robert J. Glaser, acting University President, said the administration of the Medical School is very pleased by the faculty action.

A statement issued by the Black Student Union at the University said:

"The BSU and the Medical School have reached a tentative agreement on a program to increase minority enrollment starting September, 1969. Although 10 places are being held for minority students, this will not act as a limiting quota. The BSU and the faculty senate will meet in the coming week to work out the details of the program. We of the BSU would like to commend the Medical School for their prompt and constructive response."

These are the proposals adopted by the faculty senate:

--The increased minority enrollment will begin with the class of students entering September, 1969.

--Minority students be defined as students of educationally deprived racial or cultural groups in the United States.

--Ten places in the entering class be reserved for minority group students and if 10 students are not found for this special program, any unfilled places would open to regular applicants.

-more-

--All students admitted, regardless of the method used, will be required to complete the same requirements for individual course completion and graduation.

The faculty senate statement said that a quota system of admission is undesirable as a mechanism for the routine handling of applications. The designation of 10 places in the class is done in the spirit of an experiment in medical admissions policy for a specified purpose and it is the ultimate aim to eliminate all quotas.

The senate further recommended that this program for minority recruitment should be further strengthened by the development of a tutoring program specifically designed to assist minority group students, on request, with their studies and course work.

Earlier this year a Medical School committee on minority student problems noted that lack of representation of minority groups in the medical profession is not only a Stanford problem but a problem common to all medical schools in the nation. The number of minority students enrolled in medical schools is less than 2 per cent of the total enrollment and is getting smaller.

Contributing factors to the perpetuation of this social problem, the committee said, were high education costs, the poor quality of the undergraduate education afforded minorities, and the fact that medicine is not identified by the disadvantaged minorities as appropriate or realistically possible career.

BULLETIN/ DRAKE October 7, 1968

Leonard Drake, who received a new heart August 22, died Monday evening of pneumonia at Stanford University Hospital. Death occurred at 5:45 p.m. PDT.

The 42-year-old postal clerk from Eugene, Ore., had made a normal postoperative recovery until September 21, when he suffered a rejection episode. He contracted pneumonia and his condition became critical October 5 (Saturday). He was being treated with drugs used to suppress the body's natural tendency to reject foreign tissue. One of the major problems of organ transplantation at present, doctors explained, is that these powerful drugs also suppress the body's tendency to fight off germs, thus making patients succeptible to infections.

Drake is survived by his wife, Wanda, two children, Jimmy and Vicky, a sister, MRS. Virginia Sebring and his parents Mr. and Mrs. Albert Drake, all of Eugene.

###

Stanford's other heart transplant patients, Mrs. Georgette Larson of San Jose; Mrs. Virginia Asche of Los Altos; and Robert McKee of Palo Alto, continue to do well.

STANFORD--A bright blue shirt may have played an important part in taking Glenn Battle, night supervisor of the clinical laboratories at Stanford University Medical Center, from the test tubes and microscopes of his laboratory work to the glitter of the silver screen in Hollywood.

Battle, a frequent performer in productions at the Manhattan Playhouse in East Palo Alto and the Menlo Players Guild, recently played a prominent role in a new movie, "Take the Money and Run," written and directed by, and starring comedian Woody Allen. As a result of his part, Battle will be introduced as a new actor in the film when it is released later this fall.

When he heard that "Take the Money and Run" was being filmed on location at an old labor camp near Tracy in the East Bay, Battle decided to visit the set.

"If you want to be an actor," he says with a sparkle in his eyes, "you spend a great deal of time 'hanging around' in hopes of getting some big break."

For Battle the big break may have come.

One of the five principle actors on a Georgia chain gang with Woody Allen failed to appear as shooting was ready to begin. Those in charge of casting were trying to decide how to fill the vacant role. Battle was standing with scores of other would-be actors on the set.

"Suddenly this man pointed at me and said 'You there in the blue shirt, come here'," Battle recalls. "I looked around and saw I was the only one with a blue shirt on."

Filming of the chain gang scenes took three weeks, longer than expected. Woody Allen thought the scenes were so funny that he kept giving them a larger and larger part of the movie. Nothing could have pleased Battle more.

He is now confident that his part in "Take the Money and Run" will lead to other acting jobs and possibly to a long-term contract in Hollywood after the movie is release.

In the meantime, the actor-technologist continues to dash between the Medical Center and San Francisco where several other movies including "Daddy Goes A-Hunting" in which Battle plays a policeman, are being filmed. His role in "Take the Money and Run" has also led to possible parts in a movie and television series in Hawaii.

Battle attended Howard University for three years and graduated from North Carolina College in 1959 with a B.S. degree in chemistry and a minor in drama. After graduation he headed for New York where he acted in a repertory company in Greenwich Village. He also has done community theater and been an extra in movies in Los Angeles.

Battle came north to Stanford in 1962.

STANFORD--The faculty senate of the Stanford University School of Medicine Saturday gave its unanimous approval to proposals for increasing minority student enrollment in the School of Medicine.

In a statement issued today, the Faculty senate reiterated its concern over the problem of increasing minority student enrollment and noted that for the past six months, on the initiative of the dean and the Medical School executive committee, faculty and students have been considering mechanisms for accomplishing this goal.

Dr. Robert J. Glaser, acting president of the University, said the administration of the Medical School is very pleased by the faculty action.

A statement issued by the Black Student Union said:

"The BSU and the Medical School have reached a tentative agreement on a program to increase minority enrollment starting September, 1969. Althogh 10 places are being held for minority students, this will not act as a limiting quota. The BSU and the faculty senate will meet in the coming week to work out the details of the program. We of the BSU would like to commend the Medical School for their prompt and constructive response."

Specifically, the faculty senate adopted the following proposals:

--that a special program for increasing the enrollment of minority group students be inaugurated in the School of Medicine.

--that the program begin with the class of students entering in September, 1969.

--that minority students be defined as students of educationally deprived racial or cultural groups in this country.

--that 10 places in the entering class be reserved for minority group students.

--that if 10 students are not found for this special program, any unfilled places may be offered to students from the regular applicant pool to the Medical School.

--that all students admitted, whether by special admissions policy or regular policy shall have the same requirements for individual course completion and graduation.

The faculty senate statement said that a quota system of admission is undesirable as a mechanism for the routine handling of applications and that the designation of 10 places in the class is done in the spirit of an experiment in medical admissions policy for a specified purpose and it is the ultimate aim to eliminate all quotas.

The senate further recommended that this program for minority recruitment should be further strengthened by the development of a tutoring program specifically designed to assist minority group students, on request, with their studies and course work.

STANFORD--Dr. Richard Gorlin, director of Harvard Medical School's cardiovascular unit at the Peter Bent Brigham Hospital in Boston, will deliver the fifth John Kent Lewis Lecture at Stanford University School of Medicine Oct. 8.

He will speak on "Therapy of Coronary Heart Disease: Rationale and Evaluation" at 4:45 p.m. in Room M 106.

Dr. Gorlin, whose scientific contributions over the past 15 years have ranged through many branches of cardiology, pioneered in the introduction of hydraulics to the study of diseased heart valves. His research has included studies of the physiology and pharmacology of the coronary circulation, studies of the function of the normal and diseased heart muscle, and definition of the factors which tax blood flow to the heart.

His research has also led to new ways of evaluating the success of surgical procedures to bring blood supply into the heart.

A native of Jersey City, New Jersey, Dr. Gorlin received the M.D. degree in 1948 from Harvard Medical School and did postgraduate work at the Peter Bent Brigham Hospital and additional study in England before becoming a medical officer in the U.S. Marine Corps. He has been on the faculty at Harvard since 1956.

Dr. Gorlin is a member of the major national professional and academic societies and past president of the New England Cardiovascular Society. He received the Cummings Humanitarian Award in 1963.

Dr. Gorlin's lecture is dedicated to the memory of Dr. John Kent Lewis, professor of medicine and chief of the Stanford Medical Service in San Francisco who died in 1961. Dr. Lewis, with Stanford professors A. W. Hewlett and George D. Barnett, published some of the early work on vascular sounds, exercise and respiration.

STANFORD--Paintings by Dr. Joseph P. Kriss, professor of medicine and radiology and director of the Division of Nuclear Medicine at Stanford University School of Medicine, will be exhibited next month at the Los Robles Gallery in Palo Alto.

The exhibit of 14 canvases and 12 drawings will run from Oct. 7 to Nov. 5.

This is the fourth one-man show by Dr. Kriss and represents his work over the past two years. Dr. Kriss has previously exhibited at the Stanford Art Gallery in 1963, and at the Los Robles Gallery and the Encina Gallery on the Stanford campus in 1966.

A self-taught artist, Dr. Kriss has been painting for over 25 years. His works, done in oil pigments, range from realistic to abstract and tend to be large in size. He describes the stimuli for his abstractions as both real and imaginary scenes or events and objects of nature.

Many of Dr. Kriss's paintings are in private collections in the Bay Area, New York, Philadelphia, and Baltimore. Two of his largest abstractions are owned and displayed by Syntex Laboratories.

In addition to his painting Dr. Kriss is noted for his research contributions in the fields of nuclear medicine and radiation therapy. He has been associated with the School of Medicine since 1948.

Editors: Copies of STANFORD, M.D. are available on request.

STANFORD--Young women medical students say they have found the atmosphere free of anti-feminine discrimination at Stanford University.

Comments from women in the second-year class, the class which has the largest percentage of women in the history of the University's School of Medicine, are the subject of a feature story in a current issue of STANFORD, M.D., magazine of the Stanford Medical Alumni Association.

Some of the women said that, on applying, they had feared anti-feminine bias from the admissions committee, but were reassured by the equal chance they were given on the basis of their accomplishments and potential. Patty Tackabury, a California girl who did her undergraduate work at Stanford University as well, thought bias from male students might affect her once she entered the School of Medicine. But she has decided,". . .student relationships are natural and untainted by prejudice or competition."

Assessing the attitudes of faculty members toward the lady doctors-to-be, Nora Stephens, who has a doctor husband and one child, says "A few instructors look down on women and single them out for occasional baiting, but in general they assume that our intelligence and seriousness of purpose is equal to that of the men."

To say that the picture for women in medicine hasn't always been so rosy would be the understatement of the year.

In tandem with "Young Women in Medicine," STANFORD, M.D. carries an article which has a slightly different flavor. It is a personal memoir of her career by San Francisco woman doctor Ann Purdy, an emeritus Stanford clinical professor of pediatrics.

When Dr. Purdy applied for admission to McGill Medical School fifty years ago, she was promptly refused. "Scuttlebutt from Montreal Women's Club had it that the medical faculty had threatened mass resignations if a woman was admitted," she says in the magazine.

She tells of going instead to Johns Hopkins, "into which women had been bought on a ten percent quota by a wealthy Baltimore woman for half a million dollars when the Medical School was hard up."

Dr. Purdy is well known in medical circles for the Pediatric Cardiac Clinic she conducted at Stanford University from 1931 to 1952. Her work made possible the earliest successful West Coast heart operations on children.

-more-

These days, one of the major reasons girls give for choosing Stanford University Medical School is that its new curriculum allows a flexible timetable for obtaining the M.D. degree. Students can suit themselves in planning the number of years they will spend completing the required courses.

Highly specialized work in a particular medical field is usually reserved for the internship-residency period after the M.D.; but, meanwhile, there is more free time to pursue other academic interests.

In reply to the "why Stanford for you?" question, Texas-born Barbara Anne Carroll said "the extensive and liberal concepts of medical education" had attracted her. Since becoming a medical student, she has taken advantage of nonscientific courses and lectures on the campus, has spent time writing, and is training her black Arabian horse! She is also involved in hematology research.

But having chunks of free time available during student days is no guarantee of enough time to do everything later on, when the trick will be to handle what the magazine calls "the triple role of doctor, wife and mother."

What are the girls' views about being able to play all three parts?

Barbara Manroe, another Texan, who comes from a family of five generations of doctors, put forth her feelings clearly. "For any career woman who wants her marriage to be meaningful and successful, the priorities must be . . . husband and family first, and occupation second. Any woman in medicine faces a very difficult decision . . . . . if she believes that the only way to be a good doctor is to hold it as more valuable than anything else, then she should choose not to marry . . . . . (but) if I ever come to feel that I cannot be a good doctor and a successful mother and wife, then I will give up medical school."

Virtually all of the girls were optimistic about managing the three roles, however. And their optimism is probably a natural outgrowth of the fact that they already have numerous activities in widely ranging fields. Margaret Keenan, married to a doctor, majored in English literature at the University of Minnesota and minored in chemistry. Her extra time now is spent on courses in modern dance and psychiatry, and more literature courses. She has also worked on a study of suicide attempts.

"The roles of wife, mother, and doctor need not be conflicting;" says Mrs. Keenan, "A woman in medicine must maintain the flexibility to be able to respond to the unique demands of each role as it is necessary."

STANFORD--Dr. Sherman M. Mellinkoff, dean of the University of California School of Medicine at Los Angeles, will be the featured speaker at the Stanford Medical Alumni Association's annual Big Game meeting Friday (NOV. 22).

He will speak on "The Meanings of Medical Student Unrest" during the afternoon program which will be held at the Fremont Hills Country Club in Los Altos Hills.

Dr. Mellinkoff, who received both his A.B. (1941) and M.D. (1944) degrees from Stanford University, has been dean and professor of medicine at UCLA since 1962. A noted gastroenterologist and teacher, Dr. Mellinkoff has more than 100 publications to his credit in his specialty field and in medical education.

Following registration and welcoming remarks at the Medical School, clinical presentation will be given by members of the faculty, beginning at 9:45 a.m. in Room M106. Scheduled are "Facial Signs of System Disease," by Dr. Eugene M. Farber, professor and head of the Department of Dermatology; "Dr. Jekyll and Mr. Hyde in the Sleep Lab," by Dr. William C. Dement, professor of psychiatry; and "The Prevention of People: A Study in Clinical Pharmacology," by Dr. Sumner M. Kalman, professor of pharmacology.

The ladies' program will feature a guided tour of the Hoover Institution and Memorial Church, leaving the Medical School at 9:30 a.m. and returning at noon.

Luncheon for alumni, wives, and faculty will be held at 12:30 p.m. at the Fremont Hills Country Club.

A report on the state of the Medical School by Acting University President Dr. Robert J. Glaser will lead off the afternoon program at 1:30 p.m. Remarks by Dr. Mellinkoff will conclude the day's activities.

Science Writers: Copies of papers presented at the symposium on violence will be available at the Stanford University Medical Center News Bureau. The symposium will be held Saturday, November 16, from 9 a.m. to 5:30 p.m. in Room M106 of the Medical School.

(ADVANCE FOR PM RELEASE SATURDAY, NOVEMBER 16, 1968)

STANFORD--For thirty years, a clear majority of the American people have supported legislation not merely banning the mail-order sale of guns but requiring that they be registered, a Stanford psychiatrist reported today.

Dr. Edison Trickett, speaking at a violence symposium at Stanford University School of Medicine, cited Gallup Polls since 1938, which indicate that "for three decades at least two-thirds, and more often about 75 per cent, of the American people have favored more stringent requirements of registration or licensing of guns or gun owners."

The 25 to 30 per cent of the American people who oppose stricter gun control are "politically, psychologically, and demographically a 'mixed bag,' " said Dr. Trickett, a postdoctoral fellow in psychiatry.

"Thus in the black ghetto, the Black Panthers see guns as necessary for survival and registration or licensing tantamount to surrender or acquiescence to what they feel is an intolerably unjust situation. In Dearborn, Michigan, where many middle and upper-middle-class housewives have reportedly been arming themselves, protection against potential rioting and looting is also the issue.

"But the most powerful and easily identifiable organized group consistently opposing the enactment of legislation--especially that referring to registration or licensing--is the National Rifle Association," Dr. Trickett said.

He said opponents of increased gun controls argue that such controls would infringe upon our constitutional right to bear arms.

"This is essentially an ideological argument. One of the questions worthy of investigation is the symbolic meaning of 'liberty' and 'rights' as they are linked with gun legislation and what appears to be concern that we are losing control over our destiny."

"The gun is often seen as personal protection and security against life-threatening or property-threatening dangers and destructive evil forces," Dr. Trickett said. "It is reasonable to assume that this argument against stricter gun laws may be contingent on feelings of mistrust, helplessness, and a lack of external support in the face of possible danger."

One point that merits serious study is the potential cost of such individualized protection as gun ownership, he said. Such costs include harm to innocent bystanders, the tragedy of accidental shootings, and the increased danger of impulsive violence which currently accounts for over 90 per cent of all homicides, most of which are committed among family and friends.

-more-

"An ironic twist in the killing of Robert Kennedy is instructive," Dr. Trickett said. "The allegedly used by Sirhan Sirhan was originally purchased by a white man for protection after the Watts riots of 1965. In time the gun passed through other hands on the way to Sirhan.

"In this way the instrument of one man's presumed defenses became the very instrument for killing another American."

Another question that needs critical evaluation is whether or not gun control legislation is effective in reducing crime and violence, he said. Associated with this question is the advocacy of stronger and even cruel punishment of criminals who have used guns in their crimes.

"The assumption that more severe punishment would serve as a deterrent remains undocumented," Dr. Trickett stressed. "In fact the evidence that more than 75 per cent of the homicides and 66 per cent of the criminal assaults occur among family and friends suggests the assumption that only hardened criminals commit crimes involving guns is questionable."

A considerable amount of the opposition to stricter gun laws comes from those concerned about being restricted and deprived of hunting and gun collecting privileges, "While a law requiring registration would indeed represent an inconvenience, it would deprive no one of the hunting life unless he was a convicted felon, addict, or other person specifically excluded by the most recent law," Dr. Trickett pointed out.

Another issue is that stricter gun legislation would diminish the revenue collected from ting license fees and sales taxes on guns and ammunition.

"Economic arguments seem to be a factor," the Stanford psychiatrist said. "Such antagonists of gun legislation as the National Rifle Association and the National Shooting and Sports Foundation are supported extensively by gun and ammunition manufacturers."

"If effective and mutually satisfactory resolution of the gun problem is to occur, opposing groups need to bring the hidden issues into the open, sort out the rational and irrational components of arguments, and provide each other with a means of reducing distortions and increasing trust. As the situation is now, both sides of the controversy damage their arguments by selected and distorted use of statistics," Dr. Trickett concluded.

Another speaker at the symposium, Dr. J. Chris Gillin, reported that the Committee on Violence at Stanford recommended the registration of all guns.

He said: "Since guns are involved in so many deaths and crimes, clearly the practical thing is to control guns and see if this legislation reduces death or crime rates. Registration of guns would enable proper studies to be done. Registration of guns should not be discriminatory against gun owners; it offers the opportunity for education about the risks of gun ownership."

"Just as we advertise the dangers of drinking and driving, we need to alert the public to possible dangers of gun ownership."

In comparing deaths due to firearms in the United States with those in other advanced nations, this country leads not only in homicides but suicides and accidents, Dr. Gillin pointed . Last year guns were involved in the death of over 21,000 civilians in the United States--00 homicides, 11,000 suicides, and 2,800 accidents.

"Our homicide-by-gun rates is 35 times that of Germany, Denmark and England and 7 times that of Canada and France," he noted.

Co-author of Dr. Gillin's presentation was Dr. Frank M. Ochberg. Co-authors of the report by Dr. Trickett were Dr. David M. Daniels, Dr. Jared R. Tinklenberg, and Dr. Jay Jackman.

(ADVANCE FOR PM RELEASE SATURDAY, NOVEMBER 16, 1968)

STANFORD--Two Stanford University psychiatrists today recommended that presidents and presidential candidates be prohibited by law from close contact with large crowds when their presence has been publicly announced in advance.

The psychiatrists, Dr. Robert L. Taylor and Dr. Alfred E. Weisz, told a symposium on violence at Stanford University School of Medicine that "unnecessary exposure of presidents and presidential candidates creates a situation in which the inadequate, delusional would-be assassin should have relatively little difficulty in carrying out his task."

"Mixing with the people is a strongly embedded concept in the political tradition of the United States," they said, "but it has also proved to be an accomplice to assassination.

"More effective use of mass media represents a partial solution to the unprotected exposure of political figures. But protection is virtually impossible without the cooperation the man to be protected."

Drs. Taylor and Weisz explained they are not arguing "for a reverse paranoia that results in the fear of an assassin at every street corner nor for the advisability of restricting public figures only to electronic communication. We do suggest that presidents and presidential candidates be prohibited by law from close contact with large crowds in places when their presence has been publicly announced in advance."

In discussing the history of presidential assassination in the United States, Drs. Taylor and Weisz emphasized the striking, fatalistic stance of victims such as Lincoln, Garfield and both Kennedys.

Robert Kennedy stated a view common to these four men, the psychiatrists said. They quoted the late senator as having said: "There is no sense in worrying about those things. If they want you, they can get you."

On another occasion Kennedy was quoted as having said, "I play Russian roulette every time I get up in the morning. But I just don't care. There is nothing I could do about it anyway."

This fatalistic speculation may paradoxically be a personally comforting defense against the real danger involved in being a controversial political leader, Drs. Taylor and Weisz —d. "It is as though being aware of the threat and consistently pointing it out reduces the danger."

-more-

The psychiatrists said that nine men have been involved in the eight known attempts on [illegible]es of American presidents. They were all Caucasian males ranging in age from 24 to 40. All were smaller than average in stature. With the exception of John W. Booth, Lincoln's assassin, they were unknowns, coming out of obscurity to attempt political murder.

"Each of these men had some cause or grievance that appeared obsessional, if not delusional, in intensity," the Stanford psychiatrists said.

Richard Lawrence, the first man to attempt the assassination of an American president, had suffered striking personality changes marked by unprovoked fits of laughing, crying and violence. By the time of the attempt, Lawrence's world had become a delusional one in which he was Richard III of England to whom the United States owed large sums of money. He held Andrew Jackson personally responsible for this debt.

John Booth came from a distinguished theatrical family in which the symptoms of manic-depressive illness occurred frequently. Charles Guiteau, who shot and killed President Garfield, described himself as the employee of Jesus Christ and Company. Leon Czolgosz had developed a delusion that people were trying to poison him three years before he shot McKinley.

Joseph Zangara, who made an unsuccessful attempt on Franklin D. Roosevelt's life, was a solitary bachelor who often rented two adjoining rooms to avoid others moving in. He had a fear of cold night air and was plagued by chronic stomach complaints for which doctors could [illegible]d no cause.

Lee Harvey Oswald was examined at the age of 13 by a psychiatrist at the request of the Bronx Children's Court for a truancy violation. The psychiatric report characterized Oswald as guarded, secluded, suspicious. His diagnosis was incipient schizophrenia with strong paranoid overtones and potential dangerousness.

"The inadequacy and distractability that have characterized the assassins suggests that establishing certain administrative blocks would be one reasonable approach to the problem of prevention," Drs. Taylor and Weisz said.

One such block, for example, is to require a waiting period between a citizen's announced intention to own and the actual possession of lethal weapons.

Another approach is to study the attitudes toward presidential protection to clarify the role of the victim in assassination.

"French President Charles de Gaulle has survived three assassination attempts over the past few years," they pointed out. "What are the various protection systems employed? Answers to these questions might add useful information bearing on the protection of American presidents."

(ADVANCE FOR PM RELEASE SATURDAY, NOVEMBER 16, 1968)

STANFORD--Nonviolence or "soul power" is an effective alternative to violence because instead of stimulating the adversary to fight back, it inhibits and demoralizes him, a Stanford University psychiatrist believes.

"The dynamism of nonviolence consists in its appeal to the opponent's conscience," Dr. Frederick W. Ilfeld, Jr. told a symposium on violence Saturday at the Stanford University School of Medicine.

The symposium was sponsored by the committee on violence of the Department of Psychiatry formed after the assassination of Sen. Robert F. Kennedy "in the hope of contributing to the understanding and reduction of violence in America."

He listed the key psychological ingredients in the nonviolent process--conscience, incompatible response, release of aggressive energy and masculinity.

"Nonviolence liquidates the nonviolent person's guilt feelings while at the same time activating the opponent's guilt," said Dr. Ilfeld. "To the degree that the nonviolent person acts toward the opponent in a caring, respectful manner, not only has he brought the other's guilt to consciousness, but he has made him accept this guilt."

He explained that the term "incompatible response" refers to nonviolent behavior which by its very nature inhibits a violent response.

"It is innately hard to attack someone who refuses to fight back but instead voices his concern for the attacker," he said.

He also said nonviolence provides an outlet for aggression for "it is a highly active process for the participant and monopolizes...much of his aggressive energy. It is an aggressive act but it is not an act of physical aggression."

-more-

"The practice of nonviolence," said Dr. Ilfeld, "has broken the psychological link between masculinity and violence. Participants have shown to gain a heightened feeling of manliness, a sense of moral superiority over their opponents, and increased self-respect."

He called nonviolence "a strategy which can claim all the benefits of violence without any of its limitations."

These include achieving manliness without corrupting oneself or harming others; engendering group solidarity without alienating the outsider; providing a "danger signal" to society without the stimulation of further opposition or oppression; and most important, producing meaningful social change.

In discussing strategies for bringing about social change, Dr. Ilfeld suggested:

--increasing government responsiveness to citizen needs.

--supporting the right of people to choose their government.

--establishing effective grievance mechanisms to facilitate communication between people and the government.

--preventing stagnation of the political system by enforcing retirement or office rotation of politicians.

"Rigid systems which suppress dissent are more prone to the emergence of radical cleavages and violent forms of conflict," Dr. Ilfeld said. "We must develop ways of utilizing social protest for meaningful social change, rather than suppressing or ignoring it and risking the inevitable explosive consequences."

(ADVANCE) FOR PM RELEASE SATURDAY, NOVEMBER 16, 1968

STANFORD--Every American adult, teenager, and child today is attending a "school of violence," a Stanford University psychologist said today.

Dr. Alberta E. Siegel told a symposium on violence at Stanford University School of Medicine that violence is widely portrayed on television and in the movies, both in fictional dramas and in news reports, and these media thereby "provide a school of violence for Americans."

She reminded her audience that social learning occurs not only through reward and punishment, but also by observation and imitation.

"Like other primates, man learns by watching," Dr. Siegel said. "People watch not only the social behavior of other people around them, but also the behavior of individuals portrayed in the mass media--especially movies and TV."

Color movies and television are especially compelling, noted the Stanford psychologist, because they appeal to man's two keenest senses, vision and audition, the senses through which he learns most efficiently.

"To the extent that television and film viewers accept as authentic the presentations they witness on the mass media," said Dr. Siegel, "they incorporate the behavior learned into their own repertoire of behavior, available to be performed if the relevant situations arise in their own lives.

"The distinction between fiction and reality on TV is a difficult one for normal adults to maintain, and is even more difficult for disturbed, deprived or unsophisticated adults."

"For young children, the distinction may not exist at all," she added.

Dr. Siegel is an associate professor of psychology in the department of psychiatry of the medical school. Her remarks were made at an all-day symposium on violence which highlighted reports of the committee on violence of the department of psychiatry.

The committee, chaired by Drs. David N. Daniels and Frank M. Ochberg, was formed after the assassination of Sen. Robert F. Kennedy "in the hope that as scientists, the committee members could contribute to the understanding and reduction of violence in America."

The findings will be made available to the President's Commission on Violence and to the public in a book to be published in the fall, 1969.

(ADVANCE FOR PM RELEASE SATURDAY, NOVEMBER 16, 1968)

STANFORD--The collective violence of recent urban Negro riots was caused primarily by males who tend to be the young and better educated Negroes, a Stanford University psychiatrist said today.

The rioters lack confidence that years of educational effort on their parts will pay off in terms of good jobs and fast upward mobility, and they attribute their condition to white racism, he said.

Dr. Thomas E. Bittker based his remarks on studies done since the big racial flare-ups of last year. He spoke at an all-day Stanford Medical Center Symposium on violence.

He said that collective violence apparently was chosen as a tactic in those instances, because the alternatives, non-violent and non-group tactics, "have become increasingly tedious and disillusioning for a sizable minority, currently about 15 percent of the black community."

The studies also indicate, said Dr. Bittker, that violence provides a sense of competence to the agitators which they do not experience with other forms of self-expression, and that violent tactics may make them feel more masculine and self-respecting. Hence an ideology, or romance, of violence has emerged, which, by rewarding violence, may lower the threshold of provocation.

"...we can suspect that violent gestures as they are practiced become learned; and as they become learned, they become increasingly relied upon in subsequent encounters. Thus, the most unfortunate repercussion of collective violence is the continuation of the violent process itself," he said.

However, he cited the existence of a desire in the Negro community for cultural identity. "While it (the desire) sometimes occurs in forms which seem impractical, on the whole it appears to be a positive impulse...which may, in the long run, contribute substantially to a more genuinely equal relationship between the races," he said.

Although he emphasized the shortcomings of collective violence, he also said that as a "catalyst to inter-group dialogue," it may contribute to society by awakening a "previously inattentive establishment to the needs of an aggrieved group."

He added that conclusions about a developing trend toward violence could be incorrect. "Rather than a trend toward violence, what we might be observing is the increased susceptibility of youth to novelty," he said.

EDITOR'S NOTE: Members of the press from the Bay Area are asked to indicate on the enclosed self-addressed post card if they plan to attend the violence symposium. A press conference with participants of the symposium will be held at 12:15 p.m. in Room M112 of the School of Medicine.

Violence will be the topic for an all-day symposium Saturday, Nov. 16, at Stanford University School of Medicine.

The symposium, presented by the Committee on Violence of the Department of Psychiatry at Stanford, will begin at 9 a.m. in Room M106 of the Medical School. It is open to the public. Co-chairmen are Dr. David N. Daniels, assistant professor of psychiatry, and Dr. Frank M. Ochberg, a resident in psychiatry.

"The Committee on Violence was formed after the assassination of Senator Robert F. Kennedy in the hope that as scientists, the committee members could contribute to the understanding and reduction of violence in America," Drs. Daniels and Ochberg said.

Reports and recommendations to be presented at the symposium will be submitted to the Commission on the Causes and Prevention of Violence appointed by President Lyndon B. Johnson and headed by Dr. Milton Eisenhower.

The morning session will be opened with a welcome by Dr. David M. Hamburg, professor and executive head of the Department of Psychiatry. Presentations to follow include:

9:10 Mass Media and Violence by Dr. Alberta E. Siegel, associate professor of psychology in psychiatry, with discussion by Dr. Albert Bandura, professor of psychology.

9:55 Biological Aspects of Violence by Dr. R. Charles Boelkins, research associate, with discussion by Dr. Sherwood L. Washburn, professor of anthropology at the University of California, Berkeley.

11:00 Firearms Control and Violence by Dr. J. Chris Gillin, resident in psychiatry.

11:20 The Gun Law Controversy by Dr. Edison Trickett, postdoctoral fellow, with discussion by Professor John Kaplan from the Stanford Law School.

The afternoon presentations will begin at 1 p.m. with a report on The Phenomenon of Assassination by Dr. Robert Taylor, resident in psychiatry. Also scheduled for the afternoon are:

1:40 The Choice of Violence for Resolution of Conflict by Drs. Frederick W. Ilfeld and Thomas Bittker, residents in psychiatry.

2:30 Mental Illness and Violence by Dr. George D. Gulevich, assistant professor of psychiatry.

Following the reports, a summary of the presentations and recommendations will be given by Dr. Thomas A. Gonda, professor of psychiatry and associate dean of the Medical School, and acting director of Stanford University Hospital.

At 4:30 p.m., small group discussions will be held to further explore the various aspects of violence discussed during the day. The audience will be invited to participate.

ALBUQUERQUE, N.M.--Edicational opportunities for Mexican-Americans at Stanford University School of Medicine will be discussed Saturday afternoon (December 21) on the University of New Mexico campus in Albuquerque by a Stanford University neurosurgeon.

Dr. Jose Aguilar, assistant professor of surgery and chairman of the minority search committee at Stanford University School of Medicine, Stanford, Calif., will discuss a new Stanford program which will enable students with disadvantaged educational backgrounds to attend medical school.

The program will go into effect September, 1969, and Stanford is now conducting a search to identify deserving candidates from minority groups for admission to its medical school.

"The faculty senate of the School of Medicine," said Dr. Aguilar, "has created an unusual opportunity for undergraduate students from the population of Mexican-Americans in the Southwest to attend medical school.

"It is incumbent upon leaders in the community and also universities in the Southwest to help us in our search for students wishing to take advantage of this opportunity to become physicians."

Dr. Aguilar said that financial assistance will be provided these students to enable them to complete their studies at Stanford.

Students wishing to learn more about educational opportunities in medicine at Stanford University are urged to make an appointment with Dr. Aguilar by contacting Dr. Robert S. Stone, dean, School of Medicine, University of New Mexico, Tel. 277-2321.

STANFORD--At Stanford University School of Medicine the office for Student Affairs will be headed by two associate deans.

Dr. Bernard W. Nelson has been promoted to associate dean in that office, and Dr. William P. Creger, formerly head of the Division of Hematology, is joining him.

Dr. Nelson has responsibility for the administrative aspects of implementing the new curriculum and for financial assistance to medical students, and he also serves as chairman of the admissions committee. He is concurrently assistant professor of medical microbiology.

Dr. Nelson replaces Dr. LeRoy A. Pesch, who left to become dean of the School of Medicine and director of University Hospitals at the State University of Buffalo.

Dr. Creger's area of responsibility, as outlined by Dr. Robert J. Glaser, vice-president for medical affairs at Stanford University and dean of the School of Medicine, lies in "strengthening the advising of students in regard to their clinical training, with special emphasis on internships."

This will be a half-time appointment for Dr. Creger, as he will continue clinical teaching in medicine and hematology.

Dr. Nelson has been a member of the Stanford University School of Medicine faculty since 1965, and Dr. Creger since 1949.

(ADVANCE) FOR RELEASE THURSDAY, JANUARY 30, 1969

CARMEL, CALIFORNIA -- Early experience with heart transplants suggests that adequate function can be maintained in the new heart and that heart failure due to acute rejection can be reversed, a Stanford University research team reported today.

The team's report stressed the following points:

--a transplanted human heart responds to the need for more blood during exercise as does a normal heart;

--in addition to the electrocardiogram, there are other sensitive methods for detecting early rejection;

--rejection detected early can be reversed before there is damage to the transplanted heart;

--one of the major problems now being tackled is how to obtain maximum effectiveness from immunosuppressive drugs without altering the patient's resistance to infection.

The Stanford report, titled "Hemodynamic Findings after Cardiac Transplantation," was presented by Dr. John S. Schroeder at the 22nd Annual Meeting of the Western Society for Clinical Research in Carmel. Co-authors of the report are Drs. Edward G. Stinson, Eugene Dong, Jr., Norman E. Shumway, and Donald C. Harrison.

Their work was supported by the Division of Research Facilities and Resources of the National Institutes of Health.

"Evidence obtained from studies of four patients demonstrates that the transplanted heart functions adequately to support the circulation during mild and moderate exercise," said Dr. Schroeder. "Cardiac outputs were measured on four patients in the postoperative period and were found to be within normal limits."

He stressed that acute rejection can now be detected at an early stage. In addition to the changes in the voltage on the electrocardiogram, changes in the electrical axis of the heart and the occurrence of atrial arrhythmias also predict early rejection.

-more-

Dr. Schroeder revealed that Stanford heart specialists are using indirect methods to detect changes in the stiffness of the wall of the heart.

"These changes in stiffness occur early and correspond quite well to acute rejection," he said. "In essence, it is possible now by a number of methods to detect the occurrence of early rejection in the transplanted heart."

He explained that a theory has been developed regarding the mechanism of early rejection which can be detected by the phonocardiogram.

According to the theory, during early acute rejection episodes the wall of the heart is infiltrated with edema fluid and round cells. This accounts for the stiffness of the wall which can be recorded from the pulses and phonocardiograms.

"Unfortunately," Dr. Schroeder said, "it is not possible to detect other changes in heart function by indirect means at the time rejection occurs. It seems likely that during early rejection the heart continues to function quite well in pumping blood supply to the body."

Detection and treatment of early acute rejection is considered important in beginning immunosuppressive drug treatment at the optimum time to prevent host antibodies from destroying the graft.

Since no reliable method has been available to monitor rejection in the human patient, surgeons have walked a tightrope between too much immunosuppressive drug treatment and not enough. The former leads to controllable or difficult-to-control infections. Not enough leads to rejection.

It is hoped that if the proper immunosuppressive drug is introduced in sufficient quantity before the first full-blown rejection episode and in later crises, long-term survival of the patient may be achieved, he said.

(ADVANCE) FOR RELEASE WEDNESDAY, JANUARY 29, 1969

CARMEL, CALIFORNIA -- An important technical advance that will expedite diagnosis of heart disease was reported today by a Stanford University internist and specialist in nuclear medicine.

The new diagnostic tool, known as radioisotopic angiocardiography, utilizes a scintillation camera and accessories which enable one to record and display photographically the movement of radioactive material as it flows through the heart and lungs. The radioactive drug is given to the patient by intravenous injection. There is an audio-video tape recorder which stores the camera information for subsequent replay.

Optimal images of the heart can be obtained by playing back the video-taped pictures at selected time intervals and adjusting controls on the television monitor and on a Polaroid camera which records on film the final result from the monitor.

"The new technique," said Dr. Joseph P. Kriss, "is less traumatic to the patient than conventional methods, does not require hospitalization, can be performed in two to three minutes and involves a low radiation dose to the patient.

"It has applicability as a diagnostic screening procedure for patients with known or suspected heart disease.

"At present we regard the new procedure as a complement to existing diagnostic tools, but we anticipate that in the future in some cases the need to perform the more complex diagnostic procedures will be eliminated. We are particularly interested in exploring its applicability in children."

Conventional angiocardiography permits X-ray viewing of the heart and requires that radio-opaque material be injected through a catheter (a long, thin tube) which has been passed into one of the chambers of the heart. This procedure requires more time, and the patient is usually hospitalized.

The radioactive drug used in the new procedure is 99^m Tc-pertechnetate, which has a short half-life of six hours.

-more-

"Because of the rapid decay rate of the drug, the radiation dose to which the patient is exposed is less than that incurred by common X-ray procedures," Dr. Kriss explained.

The development of the new method was reported by Dr. Kriss and his associate, Dr. Philip Matin, at the 14th annual meeting of the Western Association of Physicians in Carmel. Dr. Kriss is professor of radiology and medicine, and head of the Division of Nuclear Medicine at Stanford University School of Medicine. Dr. Matin is a fellow in nuclear medicine.

His collaborators in the development and modification of the equipment are Dr. William A. Bonner, research associate, Department of Genetics, and Dr. Elliott Levinthal, senior scientist and director of the Department of Genetics Biomedical Instrumentation Laboratory.

Dr. Kriss' work was financed by the John A. McCarthy Foundation of Los Angeles, and a gift from an anonymous San Francisco donor. Additional funding came from the National Aeronautics and Space Administration which supports the work of the Biomedical Instrumentation Laboratory.

Dr. Kriss reported the diagnosis of a variety of different cardiac abnormalities with the new technique. In two cases unexpected metastatic heart tumors were diagnosed.

Other diagnosed heart abnormalities include septal defects (defects of the dividing walls of heart chambers), insufficiency of mitral and tricuspid valves, aortic and ventricular aneurysms, chamber enlargement, congestive heart failure, and pericardial effusion (presence of fluid in the thin membrane surrounding the heart).

"We can anticipate," Dr. Kriss said, "that the basic method will be applied for diagnostic purposes to other organs--the brain, liver, and kidneys."

Dr. Kriss is a native of Pennsylvania and holds the M.D. degree from Yale. He has been a member of the Stanford medical school faculty since 1948. His work includes numerous contributions to the field of internal medicine and nuclear medicine, particularly studies on the cause, diagnosis, and treatment of thyroid disorders, and use of radioisotopes in diagnosis and treatment of cancer and heart disease.

STANFORD--Nurseries at Stanford University Hospital have been temporarily closed to new babies because of sporadic instances of mild diarrhea contracted by a few infants in the nursery areas.

Dr. Thomas A. Gonda, acting director of the hospital, said the closing of the nurseries was taken as a voluntary precautionary measure and that the Hospital is working with state health department officials to isolate the cause of the problem.

He said that no babies have been seriously ill. The premature and intensive care nurseries have not been affected by the shut-down.

Cooperative arrangements have been made with Sequoia and El Camino Hospitals to care for Stanford community and physicians' obstetric patients. Stanford will provide house staff services at Sequoia to augment the Sequoia staff as necessary.

STANFORD--An award of $4,000 has been presented to the Cardiac Surgery Research Fund at Stanford University School of Medicine by employees of Lockheed Missile and Space Company.

The money was donated from the employees' Bucks-of-the-Month Club, a fund of voluntary weekly payroll deductions. The Club has previously supported birth defects research at Stanford.

Dr. Eugene Dong, assistant professor of surgery and head of the cardiovascular surgical research laboratories said that the funds will be used to aid in the development of antilymphocyte globulin (ALG), a powerful medication which has been used to suppress the body's natural tendency to reject foreign tissue such as a transplanted organ. A centrifuge will be purchased for use in the research project.

"Investigation of the human immune system will have implications not only for heart transplants, but for transplantation of other organs as well as other medical problems such as arthritis," he said.

In accepting the Lockheed employees' award, Dr. Dong pointed out that "contributions from the private sector of our economy have always been of great importance. These contributions are of even greater significance because of the current reduction in federal support for medical research."

STANFORD--Stanford University heart surgeons say that Lizeta Guerrero is the littlest baby they have ever performed heart surgery on.

She weighs only one pound, five ounces.

The tiny infant is reported doing well after a delicate operation on Tuesday, January 21, to correct a heart disorder known as patent ductus arteriosus, which affects some premature infants.

Lizeta, daughter of Isaac and Carmen Guerrero of San Jose, was born December 27, two and a half months before her "estimated time of arrival." She was delivered at the Kaiser Foundation Hospital in Santa Clara and brought to Stanford's premature research center the same day. There, physicians determined that the duct between her aorta and her pulmonary artery had failed to close automatically at birth, as it usually does in full-term babies.

In the fetus, this duct allows the blood, already oxygenated by the mother's body, to bypass the lungs. But at birth a change in pressure takes place, causing the lungs to receive the blood. Lizeta's lungs were receiving too much blood because the duct was still open, and she developed congestive heart failure. The duct had to be closed surgically to take the overload off her lungs.

The operation was performed by Dr. Patrick Daily, a member of the cardiovascular surgery team at Stanford.

Chest X rays now show that her lungs can do their work properly. And her pediatrician, Dr. William Gill, says she is doing well in every other respect.

Still, she has a long pull to make--even "regular premies" aren't allowed to go home until they are five pounds and gaining.

Mrs. Guerrero has three other daughters, all of whom weighed in at birth in the eight to nine pound range.

STANFORD - If any kind of treatment can save her little son's eyesight, Mrs. Angela Savino of Italy is willing to try it.

Courage, and the active support of her family and the Italian people have brought her and her three-year-old, Roberto, all the way from the village of Santa Maria a Vico, in the province of Caserta, Italy, to Stanford University Medical Center. The boy has retinoblastoma, a cancer of the eye which affects 1 child in 30,000.

At Stanford, Roberto is under the care of Dr. Frank C. Winter, the ophthalmologist whose experimental treatment of a Berkeley, Calif., child for the same disease was the subject of an article carried in newspapers around the world in September of last year.

An Italian journalist who knows the Savino family noted the similarity between the two cases and pointed it out to Luigi Savino, Roberto's father. By the end of September, the Italian press was in the midst of a campaign to raise the funds necessary to send the boy to the U.S.

The Savino family, and those who sent them money, hoped Dr. Winter could use cryosurgery on Roberto's right, and only sighted, eye. (His left eye had to be removed due to retinoblastoma when he was 19 months old.)

But cryosurgery, a process of repeated freezing of the tumor cells using a tiny probe containing liquid nitrogen, couldn't be employed when the boy arrived at Stanford in late October, because the tumor in his remaining eye had grown too large.

Instead, he had to be treated with the Stanford medical linear accelerator in the hope that radiation would shrink the tumor enough so that cryosurgery could be tried.

By the third week of January, Dr. Winter was able to tell Mrs. Savino that the tumor was about 50 percent smaller, but that it might be as long as two months before he would know whether the tumor had shrunk enough for cryosurgery.

The mother is bravely waiting out the weeks, which have already seen her in a strange country over the Christmas holidays and may keep her far from her husband and two older sons right through Roberto's fourth birthday, Mar. 25. She and the boy are cared for by members of the Italian American community while they are staying in the Palo Alto area. Mrs. Gina Daniel, formerly on the staff of the Italian Consul General of San Francisco, heads up the volunteers who are helping Mrs. Savino with transportation and interpretation.

Roberto entertains himself with the toys well-wishers have given him, including an electric train with a conductor who walks through the cars shouting for tickets. The blond, curly-haired boy is too young to understand all that is happening to him, but his lively personality helps to sustain this major effort in his behalf.

Dr. Winter, who cannot estimate the chance for success with the boy at this time, says, however, "At least now there is some hope, whereas there was no hope before." ### 1/22/69

Suited Italian style, little Roberto Savino reaches out to touch the fundus camera used by technician Gisela Goetsche in his examinations at Stanford University Hospital. The boy's mother, Mrs. Angela Savino, is at the right.

STANFORD--A new complex of three separate temporary buildings is providing needed office space at Stanford University Medical Center.

Housed in the buildings are the School of Nursing, the Division of Physical Therapy, Medical Photography and ACME (Advanced Computer for Medical Research) personnel. The new facilities were opened late last fall.

"The critical space shortages in many departments made it apparent early in 1968 that additional space had to be provided at the Medical Center," says John W. Hornback, resident architect for the School of Medicine. "The problem had to be solved as quickly and as efficiently as possible. The solution was to construct a temporary, yet well constructed facility using prefabricated modules. To minimize expenses, the space was planned for basically non-laboratory departments that do not require elaborate facilities."

It is expected that the buildings, located just south of the Center, will remain for a period of about five years. By that time, the new Basic Sciences Building and the new Stanford University Hospital addition should be constructed, permitting the occupants of the temporary buildings to relocate to permanent quarters.

The total area of the three units, designated Temporary Buildings A, B and C, is approximately 11,200 square feet. This does not include the wooden decking which surrounds the entire complex and connects the three units. Total cost of the project was estimated at $275,000.

STANFORD--The Louis B. Mayer Foundation of Los Angeles has made a gift of $125,000 to the Stanford University School of Medicine to expand its cancer treatment facilities.

Benjamin H. Swig, a foundation trustee and chairman of the Fairmont Hotel Corporation, made the announcement and check presentation earlier this week at Stanford University Medical Center.

The Mayer gift brings the total raised for expansion of Stanford's radiation treatment facilities to $870,000, still short of the $955,000 goal.

When complete, the fund will enable the Medical School to treat the influx of cancer patients now on waiting lists at the Medical Center.

Planned are installation of a third medical linear accelerator, replacement of an old model, and addition of support facilities such as examining and dressing rooms.

"Because of lack of facilities, new patients must often wait four weeks for their first appointment and some people desiring treatment must be sent elsewhere," said Dr. Robert J. Glaser, vice-president for medical affairs and dean of the Medical School.

" Expanded facilities," he added, "would allow for the treatment of 25 to 30 per cent more cancer patients."

Stanford's original radiotherapy facilities were built in 1959 around an experimental high-energy physics device, the linear accelerator. Under the leadership of Dr. Henry S. Kaplan, professor and chairman of the Department of Radiology, Stanford radiologists adapted the supervoltage device for medical application in the treatment of malignant disease.

Today nearly 2,800 treatments for various types of cancer are given each month with existing equipment and personnel operating on a 10-hour basis each day, according to Dr. Kaplan.

The fund drive for the project began last March under the direction of Paul A. Bissinger, Sr., prominent San Francisco businessman.

-more-

Bissinger, a former cancer patient himself who says he owes his life to the treatment he received at Stanford, organized the "Friends of Radiology" in hope of raising funds needed for expansion of the cancer treatment center.

"It is only because I spent hours with scores of other patients in the busy, cramped quarters at Stanford that I realize how fortunate I was to have been treated," he said at the beginning of the fund drive. "If we are able to financially help with the expansion of facilities at Stanford, to give more cancer victims the chance we were given, perhaps our debt of gratitude will partially have been paid."

The Mayer Foundation, founded in 1947, was endowed by Louis B. Mayer of the Metro-Goldwyn-Mayer Corporation. Mr. Mayer, who died in 1957, was a patient of the late Dr. Arthur Bloomfield, a Stanford professor of medicine and one of the most distinguished internists in America.

In recent years the Foundation has aided numerous Stanford medical students through the Louis B. Mayer fellowships and scholarships. Other officers of the foundation are Daniel Mayer Selznick, vice president, of New York, and Myron S. Fox, secretary-treasurer, of Los Angeles.

Bissinger said there have been more than 500 donors to the campaign, with some of the largest gifts ranging from $2,500 to $21,000.

Major donors including Bissinger are: ATHERTON, Jack S. Euphrat; BEVERLY HILLS, Mrs. Carl Naumann; CHICAGO, Allen Grawoig Foundation; FRESNO, Gilbra Corporation; LIVERMORE, Ernest A. and Karl L. Wente; PEBBLE BEACH, Mrs. Ethel M. Clark; SAN FRANCISCO, Robert Minge Brown, The Mervyn L. Brenner Foundation, Carrie Baum Browning Trust, William G. Irwin Charity Foundation, Ralph K. Davies, Mrs. H. N. Kuechler, Jr., Jacob Gould Schurman III, and Lucie Stern Trust; SAN JOSE, Dr. Thomas L. Blanchard and Stella B. Gross Charitable Trust; WHEELING, WEST VIRGINIA, Dr. Joseph L. Farr.

STANFORD--A graduate student at Stanford University sees medicine's success as growing increasingly contingent on its ability to utilize technology.

Stockton-born William R. Brody, 25, preparing for that day, is studying for a doctoral degree in electrical engineering as well as a medical degree.

"Until we have people who are trained in both fields, we are going to have a hard time bringing powerful engineering techniques to bear on clinical medicine," he says. But his guess is that more and more engineering students will enter medical school. "There may be fewer people now who want to go out and build bombs," he says.

Technology's most valuable tool, the computer, is beginning to be "brought to bear," he explains, in at least three areas of medicine: basic medical research, patient monitoring and more efficient delivery of hospital care. Other applications, including the use of computers to educate doctors, may be just over the horizon.

Bill doesn't know yet which area interests him most.

An example of the computer applied to research is the work going on in a Stanford University School of Medicine neurology lab. There, the computer is doing laborious analyses in a study of how body movements are controlled. The study may someday contribute to better therapy for correcting abnormal limb movements caused by neurological diseases.

"Patient monitoring, such as that done in intensive care units, can be automated to the extent that computers will be able to provide around-the-clock surveillance and alert the medical staff as soon as an abnormality occurs," says Bill. "And computers will be able to help the hospitals of the future run wards, locate medical information and tabulate test results."

Bill started his college education at MIT, where he took the S.B. in electrical engineering in 1965 and the S.M. in 1966. A summer job between his junior and senior years at Stagg High School in Stockton played an important part in his choice of schools; he worked alongside a graduate of the famed institute on a National Science Foundation grant.

-more-

Three summers later, with two years of MIT under his belt, another summer job, this time on a California Heart Association Fellowship, brought him into the medical camp. "I worked under a pediatric surgeon at Children's Hospital in San Francisco," says Bill, "and the exposure to physicians was the key factor in my decision to go to medical school."

His father, an ophthalmologist, had encouraged him since boyhood to "work at whatever I wanted." It turned out that Bill wanted, and excelled at, biology and math and physics, so he has opted for the double doctorate.

The winner of the 1964 Scott Foundation Leadership Award as the most outstanding student in his class at MIT, Bill also received the Hewlett-Packard Biomedical Engineering Fellowship at Stanford in 1967. He currently holds a Life Insurance Medical Research Foundation Fellowship.

He admits to thriving on being busy, squeezes in a game of water polo whenever he can.

"I don't have such a thing as a 'typical schedule,'" he says, "every day is different."

His heavy schedule is workable, because Stanford University School of Medicine offers a flexible timetable with free hours to pursue other academic interests.

But the days of as many as seven finals in one week are behind him--on the engineering side he is now in the early stages of his doctoral thesis.

He is married to the former Wendy Hull of Stockton.

An urgent appeal for blood was issued today by Stanford University Medical Center.

"The situation is critical," according to Dr. Paul L. Wolf, director of the clinical laboratories at the Medical Center. "We are experiencing an average shortage of 50 units a day, particularly in the A-positive, A-negative, and O-negative blood types."

Dr. Wolf pointed out that some elective surgical procedures have had to be cancelled because of the blood shortage and said that Stanford is "barely able to keep up with emergency needs."

Over 50 operations are performed on an average day at Stanford with from six to twelve emergencies expected daily. Approximately 1200 units of blood are required each month. As an example, an open heart operation requires sixteen units of blood. An average of 30 open heart surgeries are performed each month at Stanford.

Dr. Wolf said the blood shortage, which is prevalent at all hospitals in the area, can be attributed to the holiday season when many usual donors are too busy to give blood, the increase of accidents during the holiday season, and the spreading incidence of flu in the area. He pointed out that people wishing to donate blood must be free of infection for two weeks following an illness such as the flu.

Those able to donate blood are urged to contact Irwin Memorial Blood Bank in San Francisco, Peninsula Blood Bank in Burlingame, the American Red Cross in San Jose, or the Community Blood Reserve in Palo Alto. The blood bank at Stanford University Medical Center is able to draw blood on a limited basis from 18 persons each day, a majority of whom are being drawn temporarily from the Community Blood Reserve.

STANFORD--A new course, designed to make future doctors aware of the legal issues and procedures in their field, will be offered by the Stanford University School of Medicine during the winter quarter.

The course, titled "370--Seminar in Medical Jurisprudence" in the current medical school catalog, will be offered as an elective for credit to interested medical students by members of the Santa Clara County Bar Association.

Ten lectures will be given weekly Tuesday at 7:30 p.m. in Room M112 at the Medical school beginning January 7 and ending March 11, 1969.

Faculty, Stanford University hospital professional personnel, and community physicians may also audit the lectures, according to Dr. Bernard W. Nelson, associate dean. The sessions, however, will be focused on the student participants.

The seminar is under the direction of Charles G. Schulz, a Palo Alto attorney and member of the Santa Clara County Bar Association's Medical-Legal Liaison Committee.

Subjects for discussion will range from problems of medical care over the patient's objection to "hangups" of poverty medical care, psychiatry and the law, the role of the doctor in court, drugs and society, and legal problems of tissue transplantation.

It was the Medical-Legal Liaison Committee, according to Schulz, which provided the impetus for the new course while searching for ways in which doctors might gain a better understanding of the law and lawyers.

"We recognized," he said, "that most practicing physicians are so busy they would not take the time to attend a series of meetings. It seemed desirable to reach the doctors at an earlier stage of their training."

-more-

He added the medical school environment also seemed ripe for the introduction of the course since Stanford has recently liberalized its medical curriculum and has attempted to offer more courses from which students can select their own programs of study.

Dr. Nelson said the faculty is enthusiastic about the new course taught by practicing lawyers. He feels medical students are inadequately prepared on legal aspects of medicine. Extra-curricular lectures on this subject in the past have not been sufficient to meet the need, he said.

Each of the 10 lectures, said Schulz, will be given by an individual who is well qualified to lead the discussion of the particular subject. One session will be led by Dr. Stanley A. Skillicorn, past president of the Santa Clara County Medical Society and past president of the Economic Opportunity Commission of Santa Clara County. He will discuss various institutional responses--government and private--to medical care for the disadvantaged.

"One of the functions of the course is to consider how legal decisions are made," Schulz said. "Hopefully, the physicians will then appreciate some of the limitations inherent in the legal system and why specific answers cannot be given. In turn, the lawyers will receive some impression of how their field looks to a critical outsider."

In addition to Schulz and Dr. Skillicorn, other lecturers for the course include Nordin F. Blacker, William A. Ingram, Norman W. Saucedo, John E. Lehman, David W. Leahy, Professor John Kaplan, George H. Norton, Professor Aidan R. Gough, and Ralph J. Gampell.

STANFORD--Dr. Judith Pool, senior research associate in the division of hematology at Stanford University Medical Center, has been honored with the Dr. Murray Thelin Award of the National Hemophilia Foundation.

She received the award for her "outstanding achievements which have contributed so much to the health, comfort and hope of hemophiliacs."

Hemophilia is the hereditary ailment which causes excessive bleeding. It appears only in males, and is estimated to afflict 1 in 10,000.

Dr. Pool discovered a simple method of isolating the blood's antihemophilic factor (AHF) in 1965. She froze fresh plasma, then thawed it in the cold and centrifuged it, producing a concentrate of the clotting factor which can be easily made by blood banks.

Dr. Murray Thelin, who was a hemophiliac himself, went on to produce a highly effective powder form of this AHF in 1966. He benefited from his own AHF research, but died of a heart attack late the same year.

Current research is aimed at preventing waste of the limited blood supply. "By separating blood into its five major components, and administering only the component needed by each particular kind of patient (for instance, not only hemophiliacs, but transplant patients, other surgery patients, mothers in childbirth)," says Dr. Pool, "we hope to someday assure maximum utilization of donated blood."

STANFORD--A system for monitoring babies while they are being born could help alleviate infant mortality and permanent brain damage in newborns, says a Stanford obstetrician.

"A significant portion of stillborn births can be attributed to complications encountered by the fetus while it moves down the birth canal prior to delivery," according to Dr. Robert Goodlin, associate professor of gynecology and obstetrics at Stanford University School of Medicine. "A system for monitoring the fetus during this crucial period can alert the physician to potential problems and enable him to begin procedures to ensure the delivery of a healthy baby."

The monitoring device under design and modification by Dr. Goodlin is simple and painless to mother and child. A small suction cup is attached to the head of the fetus for the five to eight hours that the expectant mother is in labor. Wires from the attachment lead to a console which records and analyzes the rate and function of the fetal heart. Physicians and nurses continually check the recorded data for any indications of an abnormality in the birth process.

"As high as 15 per cent of all babies demonstrate some degree of fetal distress before delivery," Dr. Goodlin says, "but the problem is recognized as truly serious for only 2 per cent."

The causes of the distress are varied. During the period of time when the fetus begins to move down the birth canal, the umbilical cord may be constricted by the fetus, cutting off its circulation; the mother may go into shock, thus depleting the oxygen and blood supply to the fetus; or the placenta, the organ which transfers nutrients to the fetus through the umbilical cord, may separate too early from the mother, choking the blood and oxygen supply to the baby.

"If these complications are sustained by the fetus for any length of time without detection and corrective procedures, the risk is very great that the baby will be stillborn or suffer permanent brain damage," Dr. Goodlin stresses.

-more-

Fetal distress may be of a minor nature, necessitating only that the position of the mother be changed. More serious problems may indicate the need to augment the delivery, to perform a caesarean section, or to administer oxygen to the mother to increase the supply to the fetus.

Stanford's monitoring system is complemented by a compact laboratory within arm's reach of the attending physician and staff in the labor room. Here analysis of blood samples taken, if necessary, from the scalp of the fetus may further aid the physicians in determining the cause and seriousness of the fetal distress. The specially equipped labor room was provided by Mr. and Mrs. Marron Kendrick of Atherton.

The Kendricks, parents of four grown children, lost five other infants because of miscarriage or premature birth.

"When such a tragedy strikes a young couple, they ask 'Why'?" Mrs. Kendrick says "No answer truly helps to ease the grief and anxiety. Because we had suffered these same feelings, my husband and I decided to financially support medical research aimed at understanding and combating these problems of infant mortality."

At present the monitoring system is used on a voluntary basis by mothers delivering babies at Stanford University Hospital.

Ideally, and if adequate financial support were available, Dr. Goodlin envisions all labor and delivery rooms being equipped to monitor fetal distress. The recorded data would be fed into a central console unit attended on a 24-hour basis by a technician who would alert the staff to any problems.

"It is then that we would begin to see a reduction in stillborn births and brain damage that result from complications just prior to delivery of babies," Dr. Goodlin says. "At present, implementation of such a program has been hampered by recent cutbacks in federal support."

NEW YORK--Using ultrasound, a new technique similar to naval sonar, Stanford University researchers can now detect heart changes that lead to early rejection in heart transplant patients.

The high frequency sound waves are an addition to other sophisticated techniques being used to detect rejection early enough to reverse it before the transplanted heart suffers serious damage, the researchers said.

Early rejection is the crisis that most often proves fatal in the heart transplant operations so far attempted. More than 100 operations have been performed in the world over the past year, with approximately 20 to 30 per cent survival for three months or longer.

During early rejection the heart cells fill with fluid and the heart muscle walls swell and stiffen. These danger signals can be detected by ultrasound signals bounced against the stiffening muscles.

"The changes detected by this ultrasound method correlate very well with the signs of rejection obtained by other available methods," the researchers reported.

Danger signals for early rejection can be obtained by watching for changes in the strength of the voltage signaled by the electrocardiogram, changes in the heart's electrical activity and in the rhythm of its contractions, and by careful listening via a "phonocardiogram" to the sounds of blood flowing from veins into the stiffened heart.

The new technique was described at the annual meeting of the American College of Cardiology here Thursday (Feb. 27) by Dr. John S. Schroeder, a postdoctoral fellow in cardiology at Stanford University School of Medicine. Co-authors of the report are Drs. Edward B. Stinson, Eugene Dong, Jr., Norman E. Shumway, and Donald C. Harrison.

The adaptation of ultrasound to diagnosis of early rejection in heart transplants was made by Dr. Richard Popp, a Stanford postdoctoral fellow in cardiology. Prior to coming to Stanford, Dr. Popp had worked as a trainee of the National Heart Institute with Indiana University's Dr. Harvey Feigenbau, a pioneer in diagnostic ultrasound.

Ultrasound recordings on heart transplant patients are made by using a commercially available machine which emits and receives high frequency sound waves. As the sonic impulses bounce against the heart wall, they are recorded and converted into electrical signals which can be displayed on a television screen.

Patients are monitored daily for changes in heart size which alerts physicians to watch for rejection.

When the crisis of early rejection is detected, the Stanford physicians begin the difficult job of administering the precise doses of drugs needed to suppress the body's immune mechanism.

"Many methods to detect early rejection are being investigaged," Dr. Schroeder said, "so that aggressive treatment for the rejection process can begin at an earlier stage before irreversible heart damage has occurred." ### Mailed February 26, 1969.

Science Writers: Copies of STANFORD M.D. available on request.

STANFORD--A Stanford University neurophysiologist reports that studies of dreaming cats lend support to a tempting theory that schizophrenia is the result of a biochemical defect in the patient.

Dr. William C. Dement, professor of psychiatry and pioneer in sleep and dream research, believes that an abnormality in the function of an essential brain chemical called serotonin gives rise to abnormal behavior by allowing patients to dream while awake.

Using a new drug which prevents the brain from producing serotonin, Dr. Dement causes cats to hallucinate, attack other cats, and behave with the curious mixture of normality and abnormality observed in persons with severe mental illness.

Brain wave recordings of the cats show the electrical pattern during the abnormal behavior to be identical to that of cats which are dreaming while asleep.

Although Dr. Dement is cautious about the new finding, he feels that dream and sleep research has moved a step closer to understanding psychotic illnesses in human beings.

"After a long and tortuous climb, we appear to have emerged upon high ground, and before us extends a wide vista in which our research goals...are clearly visible," he reports in the current issue of STANFORD M.D., the magazine of the Stanford Medical Alumni Association.

Dr. Dement and other researchers have previously shown that dreaming in humans and animals occurs during a particular stage of sleep which appears in humans with monotonous regularity every 90 minutes throughout the night.

During these dreaming periods the sleeper seems to shift his eyes to view or scan the unfolding panorama of his dream world in much the same way that he would examine situations in the real world. This nocturnal phenomenon, called rapid eye movement or REM sleep, is believed by researchers to be essential to well being.

Past studies by Dr. Dement have shown that depriving a person of REM sleep can cause mental changes similar to those of severe mental illness. The studies have also established that normal persons deprived of REM sleep for a number of consecutive nights will spend practically the whole time dreaming when they are allowed to sleep without interruption.

This is called a rebound effect and it is believed to be the mechanism which allows the body to compensate for loss of the essential dreaming or REM sleep.

Dr. Dement's most recent discovery with administering the drug to cats is that the animals do not rebound when they are deprived of REM sleep. He believes this is because their need to dream is satisfied by their dreaming while awake as expressed by hallucinations and abnormal behavior.

Still another dramatic finding reported last year in the Archives of General Psychiatry reinforces Dr. Dement's theory. -more-

A Stanford study, conducted by Drs. Vincent Zarcone, George Gulevich, Kazuo Azumi, and Terry Pivik, showed that actively ill schizophrenic patients failed to show the rebound effect when deprived of dreaming.

"In all our years of studying the effect of REM sleep deprivation in normal human volunteers, cats, rats, and mice, and even a monkey or two we had never failed to observe this compensatory elevation or rebound in REM sleep," writes Dr. Dement.

The important finding was confirmed by further studies of actively ill schizophrenics and, moreover, it was demonstrated that if the same patients were deprived of dreaming when they were not actively psychotic, then the deprivation was followed by a substantial compensatory rebound as in normal persons.

These findings, according to Dr. Dement, suggest that failure of the body to confine dream activity to normal sleeping periods might be the basic abnormality in the psychotic behavior.

"When the discovery of REM sleep made it possible to demonstrate that dreaming had its own biochemical regulatory mechanism," says Dr. Dement, "one could then point to a specific brain process which, given only a slight malfunction, could account for many of the puzzling attributes of the psychotic state.

"Every human brain houses a structure and mechanism that produces hallucinations, delusions, thought disorders for a substantial portion of time merely in carrying on its normal everyday activities.

"The only change that would be necessary for this structure to render its owner completely psychotic would be for it to remain turned on in the waking state."

Presently under a grant from the National Institute of Mental Health, Dr. Dement and his associates are engaged in studies to clarify and extend their observations.

"Our working hypothesis," Dr. Dement writes, "includes the possibility that there is a special nerve cell system in the brain which ordinarily functions as a drive system 'energizing' the so-called motivational behaviors.

"Dreaming or REM sleep periods provide a safety valve for this drive system by allowing it to discharge harmlessly...which may, in turn, be what gives rise to dreaming.

"The serotonin nerve cells in the brain are assumed to inhibit and regulate both aspects of this drive discharge (dreaming or behavior). If they fail to perform their function, the result is a disorganized and uncontrolled occurrence of REM activities and drive behaviors in the waking state.

"This could easily account for all attributes of the psychotic illnesses in human beings."

Studying literally miles of records of brain wave activity of lab animals is an important part of dream and sleep research. Here, in the parking lot of their Menlo Park laboratory, Dr. William C. Dement (left) and his associates, Dr. Harry B. Cohen, Kathy McGarr, Anne Sauer, Steven Henriksen, and James Ferguson, give a demonstration of the amount of work needed to analyze results of sleep research.

Douglas Allan

Death Announcement, February 25, 1969

FILE COPY

Stanford heart transplant patient Douglas Allan, a 55-year-old insurance broker from Menlo Park, died this afternoon at 3:35 p.m. at Stanford University Hospital. The cause of death is undetermined, pending an autopsy although Mr. Allan was being treated for acute rejection.

Mr. Allan received his transplanted heart on Feb. 15 from an anonymous donor. He was the 11th transplant patient at Stanford. Four others are alive.

Mr. Allen is survived by his wife, Virginia, a son, Douglas Gordon Allan, Jr., and a brother, Keith, of Santa Rosa.

STANFORD--Two department chairmen of the Stanford University School of Medicine have asked to be relieved of their administrative responsibilities to return to full-time teaching and research, effective next year.

They are Dr. Arthur Kornberg, 50, professor and chairman of the department of biochemistry, and Dr. Norman Kretchmer, 46, professor and chairman of the department of pediatrics and human development.

Both men have served on the administrative posts for the past 10 years. They assumed their responsibilities at the time when the Medical School was moved from San Francisco to the Stanford campus.

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school, made the announcement and praised Dr. Kornberg and Dr. Kretchmer for "providing the leadership necessary to launch the new programs of the transplanted medical school in their respective fields."

He added that the two men "have brought to Stanford and their departments national and international distinction."

Dr. Kornberg is recipient of the 1959 Nobel Prize in medicine for synthesizing deoxyribonucleic acid (DNA), the chemical substance that is believed to determine the heredity of living things. Last year, he and his associates reported for the first time the synthesis of fully infectious viral DNA, an accomplishment which opens the way to important progress in the study of genetics, the study of virus infections, and the nature of certain forms of cancer.

Dr. Kretchmer is internationally known for pediatric research, and for basic research in biochemistry, particularly porphyrin metabolism. He is responsible for expanding the scope of Stanford pediatric programs by focusing work on the molecular, physiologic, and behavioral aspects of growth and development. He obtained the first award from the National Institutes of Health for construction at Stanford of a Clinical Research Center for Premature Infants.

He also established a major research and training program in the field of developmental biochemistry. This is a new field which unites clinical and research efforts directed toward a biochemical understanding of congenital defects, metabolic diseases, and mental retardation.

STANFORD--Stanford University has received a bequest of $5 million from Mrs. Katharine Dexter McCormick to aid in programs at the School of Medicine, President Kenneth S. Pitzer announced today.

The gift was made in memory of her late husband, Stanley McCormick, whose father's company, McCormick Reaper, later became the International Harvester Co.

Mrs. McCormick, who died in 1967 at the age of 92, was a quiet but strong supporter of women's rights all her life. She was a founder with Carrie Chapman Catt of the League of Women Voters and served as its first vice-president.

In bequeathing the money to Stanford, Mrs. McCormick specified that it be used for the benefit of the Stanford University School of Medicine. She also expressed her hope that if the School deemed it necessary, funds could also be used "for the encouragement and assistance of women in pursuing the study of medicine, in teaching medicine, and in engaging in medical research."

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, gratefully acknowledged the gift from Mrs. McCormick and said that every consideration will be given her desire to further the role of women in medicine. He pointed out that the percentage of women presently enrolled in Stanford's medical school exceeds the national average.

Mrs. McCormick had doggedly pursued her own education at a time when it wasn't fashionable for women to do so. She attended Massachusetts Institute of Technology for three years as a special student to prepare for the entrance exams. Then she attended for another four years and received her degree in biology in 1904.

Her marriage in 1906 was shattered two years later when her husband became ill and until his death in 1947 was under constant care in their Santa Barbara estate.

During those many lonely decades, Mrs. McCormick devoted her energies and resources to programs designed to help women strengthen their roles in life.

She was always eager to support unpopular causes, as well as popular ones, in her work and charitable giving. Her assistance was very instrumental in the development of the birth control pill.

"She spent endless hours to make sure the ultimate result would be a fitting memorial to Stanley," according to a close friend.

Mrs. McCormick's great-grandfather Samuel Dexter, a lawyer, was a U.S. Senator and Secretary of War under John Adams, and later Secretary of the Treasury. Her grandfather established the town of Dexter near Ann Arbor, Mich., and helped found University of Michigan. Her father, who practiced law in Chicago, is listed in "Great American Lawyers" as one of the nation's all-time outstanding attorneys.

Science Writers: Copies of STANFORD M.D. available on request.

STANFORD -- "The fate of a drug in the body is a personal affair, as peculiar in a way as a personality trait," says a Stanford University pharmacologist.

Yet physicians today prescribe drugs as if all of their patients were the same. As a result patients are subjected to one of the most bizzare types of human experimentation, notes Dr. Sumner M. Kalman, professor of pharmacology at Stanford University School of Medicine and co-author of a new book, PRINCIPLES OF DRUG ACTION: THE BASIS OF PHARMACOLOGY.

Writing in the Winter issue of STANFORD M.D., the magazine of the Stanford Medical Alumni Association, Dr. Kalman says that "drug therapy should not resemble a plan for nuclear warfare called 'overkill.'"

"There are certain cases where we can get away with'overkill,'" he writes. "Penicillin is perhaps used in large excess, but there is almost no dose-related toxicity. The excess drug is simply wasted.

"There are other cases where the drug is being used at doses too low to have any therapeutic effect. And there are cases where a drug is used at doses that are too high for a particular individual."

Dr. Kalman cites studies by researchers at the National Institutes of Health noting the differences between fraternal twins and identical twins in the rate of metabolism of a pain-relieving drug.

"There is a three-fold variation in the biological half-time among certain pairs of fraternal twins," he states. "The most extreme variation among nine sets of identical twins was 10 per cent and most of them showed an almost identical rate of metabolism for this drug."

He says it is quite proper to assume that the degree of variation seen among fraternal twins is probably larger among unrelated persons. He quotes research done in Sweden which bears this out--a study of 11 patients maintained on the same dose of desmethylimipramine (DMI), a drug used in the treatment of depression.

There was a 30-fold range of drug concentration among these patients after they had been given the same dose for about two weeks, Dr. Kalman says.

Although an outspoken advocate of population control, the Stanford pharmacologist devotes a major part of his indictment of drug-testing and drug-prescription practices to the oral contraceptives.

"A healthy population of women in the child-bearing years, eight million women in this country alone, now serve as human guinea pigs, where a few carefully monitored subjects would have been sufficient," he writes.

-more-

He cites studies, both in England and the United States, which render oral contraceptives highly suspect as a cause of death due to deep vein thrombosis and cerebral thrombosis among some women.

The risk of death due to pulmonary embolism or cerebral thrombosis among users of oral contraceptives amounts to 1.5 per 100,000 women aged 20-34 years compared to 0.2 for a comparable control group, according to the studies. For users of oral contraceptives 35-44 years old, the risk rises to 3.9 per 100,000 compared to a death rate of 0.5 for nonusers.

Dr. Kalman feels that the side-effects of oral contraceptives are dose-related. He states that when oral contraceptives were first introduced, the first form contained about 10 milligrams of the drug. After several years this was reduced to 5 or 2 mg., and more recently to 1 mg.

"This means," says Dr. Kalman "that a very large population of women were exposed to high doses of steroids unnecessarily. Many of the women who dropped out of treatment groups here and abroad were probably distressed by annoying side actions of these hormones because high doses were used."

(Asked by this writer if he would prescribe the pill to patients, Dr. Kalman said he would provided that patients were warned of the risks. He would also do extensive follow-up of patients for signs of side-effects. "Most of the side reactions of these drugs are reversible, if diagnosed early," he said.)

"Whenever a treatment appears to be 100 per cent effective we must ask ourselves whether it is completely benign," says Dr. Kalman. "It should have been possible and it is not too late to develop guides for rational dosage-scheduling of drugs.

"Doses should be fitted to individual needs. There is no average man who always needs 400 mg of drug A or 100 mg of drug B on a certain daily schedule."

Dr. Kalman proposes that the following things be done:

. Development of techniques for measuring plasma levels of oral contraceptives and other drugs in patients, instead of reliance on conventional clues such as evidence of ovulation. "Measurement of plasma levels of hormones is not far away," he says. "It is now possible to detect as little as 1 microgram of estradiol per liter of plasma with a precision of about 5 per cent using the most advanced, modern instrumentation."

. Follow-up of individual patients more carefully. "As a patient's health changes, or other drugs are used, the plasma level of an important drug may change," he writes. "Phenobarbital and other barbiturates speed up the metabolism of other drugs. Patients generally get too many drugs. Some of these can be harmful in themselves or by causing changes in the blood level of an important drug."

. Adopting an extremely conservative attitude toward new drugs. "We need to ask ourselves," he says, "whether each new drug presents so many advantages over an established one that we must use it before we really know its hazards. It seems to me that society looks to new drugs for solutions to so many problems that the checks and balances are overwhelmed."

(ADVANCE) FOR P.M. RELEASE FRIDAY, FEBRUARY 14, 1969.

SAN FRANCISCO--A link between the use of oral contraceptives and hypertension (high blood pressure) has been established by a medical research team at Stanford University Medical Center.

In a group of 100 patients with high blood pressure, Stanford physicians found 14 women who were taking birth control pills. All of the women developed high blood pressure after they had begun taking the pills.

When oral contraceptive medication was stopped for three months, all 14 patients began to get better.

"Seven patients had normal blood pressure, four no longer required medication to control their condition, and three patients required much less medication than previously," the physicians reported.

The physicians presented their findings at the Northern California and Nevada regional meeting of the American College of Physicians in the St. Francis Hotel.

They are Dr. Myron H. Weinberger and Dr. R. Dennis Collins, postdoctoral fellows in medicine, and Dr. John A. Luetscher, professor and head of the Division of Metabolic Diseases at Stanford University School of Medicine. Their studies were conducted in the metabolic research unit of the Guggenhime Clinical Research Center supported by the National Institutes of Health.

The Stanford report corroborates observations by other investigators pointing to oral contraceptives as the most likely cause of high blood pressure among women taking such medication.

"The incidence with which hypertension develops in the normal population receiving birth control pills is not known, but is probably very small," Dr. Weinberger said.

However, a sizable number of women predisposed to high blood pressure may be taking such medication. "Withdrawal of birth control pills may represent a method of treating or curing the high blood pressure in these patients," he added.

-more-

Dr. Weinberger described Stanford studies which documented the biochemical changes in women taking oral contraceptive medication.

These are related to changes in the amount of certain hormones from the kidney (renin) and from the adrenal gland (aldosterone) which are responsible for constriction of blood vessels and handling of sodium (salt) and water.

"These changes return to normal along with the blood pressure after three months of discontinuation of the birth control pills," Dr. Weinberger said.

He noted that the factors that make some women susceptible to high blood pressure during oral contraceptive therapy are unclear.

"It is possible that various diseases of the kidneys may make patients less resistant to the changes described," Dr. Weinberger reported.

The practical message of the Stanford report is this:

. Physicians who prescribe oral contraceptives to their patients should be aware of the risk of high blood pressure.

. Patients with pre-existing hypertension may get worse after taking oral contraceptives.

. Biochemical changes in patients who take birth control pills may make diagnosis of high blood pressure difficult.

END ADVANCE FOR P.M. RELEASE FRIDAY, FEBRUARY 14, 1969.

MAILED February 11, 1969.

STANFORD--A free lance writer from Los Angeles is recovering normally this morning following a heart transplant operation at Stanford University Hospital Saturday evening.

The recipient is 43-year-old Sasha Gilien. Gilien received his new heart from an anonymous donor in an operation performed by Dr. Norman Shumway, head of cardiovascular surgery and heart transplant pioneer.

Mr. Gilien was transferred to Stanford Jan. 30 from Los Angeles, where he suffered a massive heart attack on Jan. 20. He was accompanied to Stanford by his wife, Nancy.

The patient has lived in Los Angeles most of his life. The Gilien's have an 18-month-old daughter, Thea.

As a writer, Gilien is most recently noted for scripts for the television series "Big Valley," which he co-authored with Mel Goldberg. He is also co-author with Myron Roberts and Lincoln Haynes of a new book, "Begatting of a President."

STANFORD--A three-year grant totalling $150,000 has been awarded to Stanford University School of Medicine by the Donald E. Baxter Foundation of Los Angeles.

The foundation stipulated that 20 percent of the funds be used for the medical student aid program at Stanford with the balance being available for general medical research.

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, expressed gratitude to the Baxter Foundation today and stressed that "private support of medical education and research is especially timely because of recent cutbacks in Federal aid."

"It is ironic," he said, "that medical schools are feeling the pinch of these cutbacks at a time when society is putting pressure on them to produce more doctors and to provide better health care for every citizen in this country.

"Without increased funding, both from the private sector and the Federal government, Stanford's medical school and other medical schools across the land will not be able to do the quality job they want to do and that is being demanded of them.

"We are particularly appreciative of the unrestricted nature of the Baxter Foundation Grant. This will enable us to designate funds in those areas of research most urgently in need of financial assistance," Dr. Glaser said.

The Baxter Foundation was established in 1959 in honor of Dr. Donald E. Baxter, a distinguished physician who was a leader in the development of high-quality production of solutions for mass intravenous therapy and associated medical equipment.

Dr. Baxter died in 1935. His widow, Mrs. Delia B. Baxter, resides in Atherton.

STANFORD--Kidney transplantation received a major boost at Stanford University Medical Center recently when a new renal care unit went into operation.

The new unit is self-contained, with five beds, a nurses' station, doctors' consultation room and set-up room where the artificial kidney machine accessories are assembled. Also, new intensive care equipment has been installed so that patients can come directly into the renal care unit from surgery.

The new facilities and equipment will enable the Medical Center to provide 100 dialysis treatments each month to pre- and postoperative kidney transplant patients. Each patient requires three or more treatments a week, with each treatment taking eight hours. On the average, two kidney transplants a month are performed at Stanford.

Dr. Roy Cohn, professor of surgery and head of the renal transplant program, acknowledges that the new unit will double the Medical Center's capacity to care for kidney transplant patients. But he notes that projections indicate that by 1970 "the demand for dialysis treatments will increase another three-fold."

Dialysis with the artificial kidney duplicates the continuous blood-cleansing action of healthy kidneys, removing wastes and toxins which could cause death if allowed to accumulate.

In addition to augmenting patient care, the new renal care unit will also enhance kidney transplantation research, particularly in the use of cadaver organs.

"The number of potential transplant recipients far surpasses the number of appropriate live donors," Dr. Cohn says. "This situation makes the ability to use kidneys of dead persons very important."

Working with Dr. Cohn on the kidney transplant program are Dr. Zoltan J. Lucas, Dr. John M. Palmer and Dr. Joshua Miller, assistant professors of surgery; and Dr. Norman Coplon, a postdoctoral fellow in internal medicine.

STANFORD--Visiting hours at Stanford University Hospital have been made more flexible to meet the needs of patients and their families.

Starting Feb. 1, the Hospital initiated semi-open visiting hours which begin in the early morning and conclude at 9 p.m. The nurse in charge of each patient care unit in the Hospital will be responsible for exercising proper controls for the welfare and proper care of each patient in her unit.

Previously general visiting hours at the Hospital were from 2 to 4 p.m. and 7 to 8:30 p.m. daily.

Certain regulations will continue to be maintained in special care units of the Hospital.

Patients in the Intensive or Coronary Care Units may be visited by members of their immediate family or the clergy for 10 minutes each hour. Parents of patients in the pediatric ward will have unlimited visiting privileges. Other visitors in pediatrics will be permitted at the discretion of the nurse in charge.

The State Department of Public Health has established visiting regulations in the maternity and nursery areas of the Hospital. Visitors are asked to leave the areas for an hour while infants are being fed at 9:15 a.m., 1:15 p.m. and 5:15 p.m.; children under 16 years of age may not visit in the areas; and no more than two visitors per maternity patient are permitted at any one time.

Science Writers: Dr. Bourne will deliver his paper Wednesday morning at a symposium of the American Orthopsychiatric Association in New York. Copies of the paper are available from the Stanford University Medical Center News Bureau.

FILE COPY

ADVANCE FOR PM RELEASE WEDNESDAY, APRIL 2, 1969

NEW YORK -- Basic training in the Army acts to ensure the perpetuation of the military, a Stanford University psychiatrist believes.

Dr. Peter G. Bourne, addressing the annual meeting of the American Orthopsychiatric Association today, said that the basic training experience amounts to a "critical transition" in the life of an adolescent. Our society, and the recruits, view basic training as an equivalent of a "manhood initiation rite," he added.

Plunged into an environment which is hostile and conveys the message that he is unworthy and inadequate, the inductee finds, Dr. Bourne said, that "acquiescence to the omnipotence and omniscience of the organization" is the only path to success.

The soldier thus becomes convinced of the unassailable authority of the military in its own domain, and of the wisdom of unquestioning acceptance of military objectives, the psychiatrist said.

Later on, when soldiers have returned to civilian life, they encourage "a posture of special concession towards the military" in our society, "making the military's power and influence largely immune from the criticism that plagues other government organizations."

Dr. Bourne, who has served a stint with the U.S. Army in Viet Nam, did his study of basic training while he was associated with the Walter Reed Institute of Research in Washington, D.C. Data for the study was obtained from platoons passing through their eight-week training periods at Ft. Dix, New Jersey.

Tests showed, he said, that entering the Army was an environmental shock to the young men, representing "the single most destructive threat to their adaptive capacity that they have had to endure."

"Each recruit is reminded that nothing he brought with him from civilian life means anything in the military. But for all he relinquishes he (initially) receives nothing in return," Dr. Bourne continued. "The Army has made him understand that he has no value in its society except to become a soldier, yet it does not reciprocate. For weeks he remains an outsider."

Anger and depression in the platoons reached a peak at about the fourth week of the training, Dr. Bourne reported. A "turning point" didn't come until the recruits began to acquire military skills -- hand-to-hand combat, use of the bayonet, and particularly firing the rifle.

"There is laughter and euphoria in the barracks on the night of 'record fire,' " Dr. Bourne said. "The very fact that the recruit is being tested on his ability with a rifle implies that at last the Army recognizes that he some inherent worth . . . . . For each accomplishment, he now receives ample reward from the system; his shattered self-esteem is bolstered."

Later on, said the psychiatrist, the veteran retains an element of identification with the organization which once bestowed his manly status, "perceiving any limitation of military power as an incursion of his own influence."

STANFORD--Dr. G. Robert Mason, assistant professor of surgery at Stanford University School of Medicine, has been named a Markle Scholar in Academic Medicine, the John and Mary R. Markle Foundation of New York announced today.

Dr. Mason is one of 25 young medical scientists in the United States and Canada chosen for the honor. As part of the Markle Scholar Program, the Foundation awards a five-year stipend totaling $30,000 to Stanford to "assist in the development of the Scholar as a teacher, investigator, or administrator."

Mason has been a member of the Stanford faculty since 1966. He received his B.A. (1955) from Oberlin College, his M.D. (1957) from the University of Chicago, and his Ph.D. (1968) from Stanford.

The Markle Scholar grants have been made annually since 1948 to support young medical school teachers and investigators early in their careers. The Foundation was established in 1927 by the late John Markle, a Pennsylvania coal operator.

###

STANFORD--"The Challenge of the Community to the Medical Center" will be the topic of a special lecture Thursday afternoon at Stanford University School of Medicine.

Guest speaker will be Dr. Count D. Gibson Jr., chairman and professor of the Department of Preventive Medicine at Tufts University School of Medicine. He will speak at 4 p.m. in Room M112 of the Medical School. His lecture is open to the public.

Dr. Gibson, a noted authority on community health care, is co-director of Tufts' Comprehensive Community Health Action Program. The program was created in 1965 to study means of providing comprehensive health services in deprived areas through community health centers. The centers encourage maximum participation by the community in meeting its own health needs and aid in the training of local residents as health assistants. Initial studies are being conducted in two communities, a low-income housing development in downtown Boston and an almost exclusively Black rural county in Mississippi.

Dr. Gibson received his B. S. (1942) and M.D. (1944) degrees from Emory University. He joined the Tufts' faculty in 1958.

STANFORD--A 42-year old trucker from Crescent City, California is reported in satisfactory condition today following a heart transplant operation Saturday morning at Stanford University Hospital.

The recipient is Glen Campbell. He received his new heart from an anonymous donor in a 4 1/2 hour operation performed by a team of surgeons headed by Dr. Norman E. Shumway.

Campbell has suffered a rapid deterioration of the heart muscle for the past six months. He was referred to Stanford March 14. Campbell's family includes his wife, Betty, and two sons, Steve, 17, and Harley, 15.

Campbell is Stanford's 12th heart transplant patient. Four others survive.

STANFORD -- "I somehow remember being at the hospital, sinking. There was something said about a donor and then I was in surgery. It's all a very fragmentary, dreamlike sensation."

These are the sketchy details recalled by Sasha Gilien, a free lance writer from Los Angeles, who received a transplanted heart at Stanford University Medical Center last month.

"It all began on Monday morning, Jan. 20, when I got this peculiar sensation in my chest," Gilien recalls. "I knew something terrible was happening and told my wife, Nancy, to call an ambulance. I remember arriving at the emergency entrance to Mt. Sinai Hospital and then everything goes blank."

"It's almost uncanny that a physical examination earlier in January had revealed that I was a prime candidate for a heart attack," the 43-year old writer says. Gilien's private physician had found him to be overweight with a cholesterol count and blood pressure that were "sky-high", and in need of regular exercise. His family history is also dotted with heart disease.

"For me the warning came too late," Gilien says.

On Jan. 29, physicians in Los Angeles told Mrs. Gilien that her husband would not recover from the massive heart attack he had suffered.

"I was told that the only possible alternative was a heart transplant," recalls Mrs. Gilien, a registered nurse. "At first I was stunned. Although Sasha and I had followed the transplants being done last year, it was difficult to believe that it could be happening to us. Once this shock had passed, there was no question but to go ahead."

Later that day the Giliens were flown to Stanford by air-ambulance. At the same time Stanford heart surgeons began to look for a suitable heart donor. The search took until Feb. 8.

"The first week or so after the operation is pretty hazy," Gilien says. "I remember asking my wife to get me a huge calendar and chatting with my nurses.

"My first thought about the operation was that of all the billions of people in the world, I am one of the few that has a transplanted heart," Gilien recalls. "It really fascinates me that after my heart attack I was in the right place at the right time for all of this to have happened."

-more-

"I also have no doubt but that the transplant saved my life. My brother Ted died of a heart attack two years ago, before transplants were being done. I've been given a chance which he never had."

Stanford physicians are also optimistic about Gilien's recovery. Dr. Edward Stinson, who directs the postoperative care of the transplant patients, says he thinks Gilien "is capable of being fully restored to a productive life."

"Since the operation was performed six weeks ago, Gilien's convalescence has been uncomplicated and his activity and strength have increased daily," according to Dr. Stinson. "He has been treated for apparent mild rejection episodes on three occasions but in each case the rejection was completely reversed."

A plus in Gilien's favor is that prior to his severe heart attack, he had no history of disease in other vital organs such as the liver or lungs. The healthy condition of these organs is thought to be a major consideration in the recovery of three other Stanford heart transplant patients who are now living at home.

Today the pecking of typewriter keys can be heard drifting from Gilien's room where he has again taken up his writing career. He has been in contact with his agent about new writing assignments and is already working on a television script idea. Gilien has co-authored scripts for the series "The Big Valley," and also co-authored a book, "Begatting of a President."

Other parts of his day are spent visiting with his wife, chatting with other patients and staff, and following the exercise program prescribed by his physicians.

"I'm getting very anxious to be released from the hospital and to resume a normal life with my wife and our baby," Gilien says. "We plan to make a new home in the Stanford area and are looking forward to it."

Stanford physicians hope to discharge Gilien by the end of the month.

STANFORD -- A cat who missed a lot of cat naps, helping man to gain a better understanding of mental illness, has stepped back into the leisure class after two years of service for science.

His name is Isch and he used to work for a Stanford University medical team as an experimental subject in sleep and dream research. Now he is a pet, but several tiny electric wires had to be removed from his head before he could return to normal life.

After a painless operation, Isch has gone to live with Kathy McGarr, a research assistant in the sleep laboratory, and her husband Bill, a graduate student in business at Stanford. Kathy says when she first took Isch home he was afraid to go more than five feet from the front door. "But now," she says, "he's not so dependent on human company. In fact, I think he is majoring in 'neighborhood exploration,' and minoring in 'sniffing'."

"He sniffs absolutely everything," she adds.

Isch and several other cats participated in studies which have led Stanford neurophysiologist William C. Dement and his team to a new discovery about the nature of mental illness and its relationship to sleep and dreaming.

The cats furnished the brain wave data which have provided clues that a defect in the function of an essential brain chemical gives rise to abnormal behavior, and seems to induce hallucinations, or dreaming, during wakefulness.

Given a drug which depleted the brain's supply of a substance known as serotonin, the cats displayed abnormal behavior while awake. Their brain wave patterns during these episodes were similar to dreaming patterns, suggesting that the animals were dreaming while awake.

"After this series of experiments, we felt that Isch had served us well, and we decided to retire him," says Dr. Harry B. Cohen, a physiological psychologist and member of Dr. Dement's research team. The medical team rehabilitated Isch, as they do most of the research animals, by performing the operation, and caring for him at the laboratory until he was ready to go home with Kathy.

Now Isch, the sniffy cat, is free to play all day. If he can stay awake.

SCIENCE WRITERS: Dr. Opler will present his paper at 5:15 p.m. Sunday, March 23, in the San Francisco Hilton.

(ADVANCE) FOR AM RELEASE MONDAY, MARCH 24, 1969.

The human body's own defenses may hold the key to survival in some breast cancers, a Stanford University researcher reported today.

Dr. Stanley R. Opler of the Stanford University School of Medicine, said he made a detailed study of long- and short-term survivors with breast cancer and demonstrated that the defense mechanism of the former had been mobilized to slow down their own cancer cells or contain them after they had established a beachhead.

"This defense mechanism may be seen at the time of diagnostic surgery in some individuals and can be evaluated by examination of the tumor and its surrounding tissue and associated lymph nodes," Dr. Opler said.

"Ways of enhancing the body's defense against cancer by stimulating the system that produces these sensitive white cells are being studied," Dr. Opler said.

He described his findings at the meeting of the American Association for Cancer Research at the San Francisco Hilton Hotel.

Dr. Opler said his study was undertaken because of the "curious finding that some patients with widespread cancer were able to survive for long periods of time without any obvious explanation while others with comparable tumors failed to survive as long."

In many of these individuals, Dr. Opler found white cells surrounding their cancer cells and a stimulated immune system was seen in their lymph nodes.

"The tumors themselves proved to be similar," Dr. Opler reported, "but these studies revealed further protective factors in the long-surviving cases which appeared to be the response of the host's white cells and lymph nodes."

Dr. Opler said these findings are in accord with the possibility that the human body's immune system may be important in keeping the cancer patient alive when the disease has become clinically evident and has spread beyond the confines of local treatment.

The so-called "killer lymphocytes," white cells sensitized against the host's cancer cells, may home in, destroying some malignant target cells.

These cancer patients' lymph nodes also have important reactive changes that were shown to be significantly associated with long-term survival and are therefore expressions of host-resistance.

Studies on the role of the immune mechanism in cancer are under investigation, he said.

Paper, FASEB Atlantic City Meeting, April 13-18, 1969

Subject	A New Unique Histochemical Method for the Demonstration of Ribonuclease
Author.	Paul L. Wolf, M.D.
Address	Director of the Clinical Laboratories, Stanford University Medical Center, Stanford, California 94305
Time.	9:30 a.m., Friday, April 18, 1969
Place	Traymore Hotel, Belvedere Room, Atlantic City, New Jersey
Program	Enzymes
Convention Address.	Columbus Hotel

We have recently directed our endeavors toward developing new techniques and substrates for the demonstration of enzymes in tissues, peripheral blood, sera, and bacterial cultures. Previously we have described the application of the indigogenic principle to the histochemical demonstration of leucine aminopeptidase, beta-glucosidase, beta-galactosidase, N-acetyl glucosaminidase, alkaline and acid phosphatase, sulfatase, beta-xylosidase, endo- and exo-nucleases (phosphodiesterases), and serum alkaline and acid phosphatase, by disk electrophoresis. We have recently synthesized 5-bromo-4-chloro-3-indolyl-thymidine-5'-phosphate and 5-bromo-4-chloro-3-indolyl-thymidine-3'-phosphate, and have utilized these substrates to localize intracellular DNase. The principle of the reaction is that the nuclease enzyme cleaves the substrate at the site of attachment of the indolyl ring to the thymidine-3'-phosphate. A highly insoluble blue-green indigo is deposited at the site of the enzyme.

Recent studies in our laboratory have led to a new indigogenic histochemical technique for the demonstration of ribonuclease which plays an important role in protein synthesis. A majority of former techniques are indirect coupling procedures or fluorescent antibody methods. A specific substrate for ribonuclease, 5-bromo-4-chloro-3-indolyl uridine 2' (3') phosphate was synthesized, modeled after the technique for the indolyl substrates for the DNases. This substrate offers the advantage of precise enzyme localization with no diffusion. The method is simple and direct, and there is no need for a coupling reaction. The biochemical principle is that ribonuclease cleaves the substrate to yield a green-blue highly insoluble indigo. Animal tissues were incubated in the indolyl uridine substrate at various pHs. The histochemical reaction time for alkaline RNase II was ten minutes at pH 7.6 and for acid RNase II two hours at pH 5.5. The enzyme localization was only cytoplasmic. Fresh frozen sections were inferior to fixed tissue sections for localization and intensity of reaction. Alkaline RNase II was found primarily in the liver and kidney, while acid RNase II was present in pancreas and other tissues. The new substrate should facilitate the evaluation of ribonuclease.

STANFORD -- If you have any secrets, be careful! Your face may give them away. You may have considered your face as serving only to give you a window on the world. But now a Stanford University dermatologist says your face also gives a window on your entire body.

The view afforded is startlingly clear.

By looking at your face, a curious, skilled, and intuitive diagnostician can discern changes and markings which provide a tip-off to scores of internal diseases, says Dr. Eugene M. Farber of the Stanford University School of Medicine.

"For example," asks Dr. Farber, "what would one make of a patient who appeared with what Shakespeare describes in speaking of Cassius, as 'a lean and hungry look'?

"One would not normally suspect such a patient of contemplated regicide, but he could be suffering from tuberculosis. He might be a victim of the malabsorption syndrome, a failure of the system to allow digested foods to be absorbed through the intestinal walls into the blood stream. Or the physician might suspect ulcers, or even anorexia nervosa, a severe nervous condition resulting in loss of appetite."

It might be, of course, Dr. Farber adds, that the "lean and hungry" looking patient simply has not been able to afford a square meal in some time. In that case it would seem appropriate for the doctor to check the patient's finances as well as his health.

The idea of the face as a window through which one can look inside the body is not new, Dr. Farber explains. The little noted and not often used diagnostic art is called pathognomy (from the Greek, pathos, plus gnome -- a means of knowing).

"Like Sherlock Holmes," Dr. Farber says, "a dermatologist can reconstruct a whole chain of events from a few details which the casual observer would miss entirely."

Dr. Farber, who is professor and head of the Department of Dermatology, has a special interest in this aspect of medicine and has published a number of papers about the skin manifestations of internal disease. He discussed his interest in the current issue of STANFORD M.D., the quarterly magazine of the Stanford Medical Alumni Association.

The well-worn expression, "You don't look well," often has for the doctor a more meaningful connotation than that of its ordinary use, Dr. Farber writes.

For example, the patient with generalized, nonspecific heart disease may tip off the ervant physician almost immediately because of a complex of facial clues: an anxious expression with bright, watery staring eyes, a tensely-held mouth, and a face that appears to be somewhat shrunken. As might be expected, this group of facial signs is known as cardiac facies.

-more-

On the other hand, the patient whose cheeks are notably shrunken, with pale and sallow complexion and the sclera (outermost coat of the eyeball) pale or bluish, may well be suffering from a heart condition known as aortic insufficiency.

A condition involving another part of the heart, disease of the mitral valve, may be tipped off by rosy, flushed cheeks and dilated capillaries.

If a patient has yellow patches, like small deposits of tallow, under the eyes or on the eyelids, chances are about fifty-fifty that he has arteriosclerosis; that his blood is thick with cholesterol or other lipids.

Many other facial clues to disease are somewhat rare, but nonetheless interesting to the physician. One might look at some of them, Dr. Farber writes, remembering what "a lady" says to Macbeth in the first act of that play:

"Your face, my thane, is as a book where men may read strange matters."

The patient whose face has a silvery sheen should be suspected of argyria, a condition resulting from the long-continued use of silver salts, as from argyrol eye or nose drops.

If a patient presents himself with freckle-like markings of the mucous membrane on the lips or inside of the mouth, it is a sure bet that he also has benign polyps of the small intestines.

"In seeing children," Dr. Farber says, "one ought not to assume that young Johnny is simply as dumb as he looks. That open-mouthed, stupid look may, instead, be a sign calling for the removal of excess adenoid tissue."

Facies hepatica includes a thin face with sunken eyeballs, a sallow complexion and yellowish eyelids. These are signs of chronic disorders of the liver.

Hives, often assumed to be a disease entity, is actually only a sign of something wrong elsewhere. These hives or wheal-like lesions, with their intense itching, may have a number of underlying causes -- sensitivity to drugs, foods or other things, or chronic infections in teeth or elsewhere.

If a patient is seen with gray or slate-blue skin, he may well have hemochromatosis, an inborn error of metabolism which results in pigmentation due to an abnormal amount of melanin in the skin.

Despite all this emphasis on the face's use as a diagnostic aid, it should not be forgotten that people do undergo facial changes which have nothing to do with disease, according to Dr. Farber.

"The man who appears to be developing an elongated face may, in fact, only be suffering the ravages of balding," Dr. Farber points out. "And it is no secret that a woman's face does not always present the clear source of clues it might. Much can be hidden from the physician's eye by pancake makeup, or even simple powder and paint."

Dr. Farber concludes with this thought: "Disease is not all. In the human face, friendship and love are good things to look for, too."

STANFORD--Dr. Thomas A. Gonda, professor of psychiatry, has been appointed director of Stanford University Hospital.

News of his appointment came Wednesday (MARCH 12) in a joint announcement by Dr. Robert J. Glaser, Stanford University vice-president for medical affairs and dean of the School of Medicine, and James E. O'Brien, president of the Hospital's board of directors. They also announced the appointment of Courtney S. Jones as deputy director of the Hospital.

Dr. Gonda and Jones had been serving in an acting capacity since July of 1968, when the University purchased the City of Palo Alto's hospital holdings and created a new entity, the Stanford University Medical Center.

In addition to the directorship, Dr. Gonda will continue as an associate dean of the School of Medicine. He joined the Stanford faculty in 1953 as a clinical instructor in medicine (neuropsychiatry), and advanced through the academic ranks, becoming professor of psychiatry in 1965. Both his A.B. (1942) and M.D. (1945) were obtained at Stanford.

Jones was formerly director of business and fiscal affairs for the School of Medicine. He joined the administrative staff of the Stanford Linear Accelerator Center in 1962, and was assistant controller and associate director of the University's computation center before joining the administrative staff of the School of Medicine. He obtained the A.B. from Brown University (1957), and the M.B.A. from Stanford (1962).

(ADVANCE) FOR AM RELEASE THURSDAY, MARCH 13, 1969

SAN FRANCISCO--Studies of guinea pigs may provide a model for the long-sought key to more successful treatment and remission of a certain form of human leukemia, a Stanford University pathologist reported today.

Speaking at a meeting of the International Academy of Pathology, Dr. Stanley R. Opler, clinical associate professor of pathology at Stanford University School of Medicine, said he infected guinea pigs by feeding them orally with spleen cells containing the leukemia virus that he originally described as being associated with this disease.

The guinea pigs developed acute lymphatic leukemia, a form of blood cancer which is rapidly fatal in children and young adults.

When the guinea pigs died of the disease, Dr. Opler removed their livers and studied them under the light and electron microscope, then compared the results to liver tissue obtained from human leukemia victims.

"The pattern of acute leukemia in the liver as seen in our study of human leukemia and in the guinea pig model was striking similar," Dr. Opler said.

"The findings have two important implications for cancer research," Dr. Opler stated in an interview. "First, the ability to produce acute leukemia with a virus in the guinea pig adds to speculation of whether the disease in humans might be caused by a virus.

"Second, one can use the guinea pig model to test new forms of therapy against leukemia which might ultimately be used in human disease because of similarity of organ involvement and clinical evolution."

-more-

Present methods of treating leukemic patients with cytotoxic drugs (drugs that kill cells directly) may lead eventually to the demise of the patient, not because they fail to destroy numerous cancer cells but because they destroy normal tissue such as liver and bone marrow, Dr. Opler explained. These drugs also suppress the body's ability to fight infections by destroying immune white cells.

"Therefore, there is a need to experiment with normal metabolites or growth inhibitors which act not by killing the cell directly but by turning off the biochemical mechanism that produces the uncontrolled proliferation of leukemic cells," he said.

"The ability to readily find viral particles in leukemic guinea pigs and to produce the leukemia orally or with the injection of the virus is a rather striking experimental demonstration of the infectious nature of the disease in the guinea pig," Dr. Opler commented.

Other animal systems that have furnished valuable leads for leukemia studies are the chicken and the mouse. But unlike the other experimental systems, Dr. Opler added, the virus has never been seen in the absence of leukemia in the guinea pig.

Although the role of a virus remains unproven in human leukemia, Dr. Opler reminded his colleagues that the studies are not without historical precedent.

"With regard to comparative pathology, the guinea pig has many similarities to man as has been demonstrated in studies relating to brucellosis, diptheria, tuberculosis and polio," he said.

Dr. Opler discovered the new virus and described its unique structure seen by the electron microscope three years ago. Recently he has published the results of experiments proving it is a cancer-producing virus.

These findings have created interest among cancer researchers because the leukemia found in the guinea pigs is pathologically indistinguishable from that seen in humans. Currently others have confirmed the presence of the Opler virus in studies with leukemic guinea pigs.

The guinea pig, however, may prove to be a significant model for human leukemia studies due to its past relevance to human disease, Dr. Opler said.

(ADVANCE) FOR RELEASE SUNDAY, MARCH 9, 1969

SAN FRANCISCO--A Stanford University pathologist today cautioned surgeons to avoid prolonged surgery on jaundiced patients because it can lead to kidney damage.

Dr. Paul Wolf, associate professor of pathology and director of Clinical Laboratories at Stanford University Hospital, pointed out that his investigation has demonstrated a relationship between jaundice and lack of oxygen or low blood pressure, which combine to produce prominent cell damage in the small tubules and filter chambers of the kidney.

He added that neither liver disease or lack of oxygen alone were capable of inducing the histochemical changes found with the combination of both conditions.

A drop in blood pressure during surgery reduces sharply the oxygen supply necessary for the kidney to survive. It is the combination of jaundice and lack of oxygen that causes the damage.

Dr. Wolf presented his findings at the meeting of the American Association of Pathologists and Bacteriologists in San Francisco.

He said the clinical significance of the study is that "one must prevent renal anoxia (insufficient supply of oxygen to the kidney) in jaundiced patients. Surgery in those patients should not be prolonged. Hypotension (diminished blood pressure) in patients with liver disease should be quickly corrected."

"Furthermore," Dr. Wolf added, "conditions such as excessive blood loss, and heart failure which may lead to renal anoxia in jaundiced patients should be quickly treated."

Dr. Wolf explained that kidney damage may be a common phenomenon in patients who have liver disease. The association of kidney failure with liver disease is known medically as "hepatorenal syndrome." The nature of the disease, first described in patients who developed kidney impairment soon after surgery of the bile duct, has been a matter of considerable controversy.

"The manner in which kidney tubules are injured in jaundiced individuals is not clear," said Dr. Wolf. But he theorized that bilirubin, one of the blood clotting proteins, may injure the kidney cells under certain conditions.

He said that bile salts may also be toxic to cells. Recent studies have indicated that abnormal amounts of amino acids, products of proteins, are present in the blood stream of patients with severe liver disease. These amino acids may damage the kidney tubules, he said.

For his studies, Dr. Wolf used three groups of animals (rabbits and dogs). In one group, the animals' renal arteries were clipped to cut off blood circulation and thus the oxygen supply to the kidneys. In the second group jaundice was induced by tying the common bile duct. A third group consisted of animals with induced lack of oxygen or low blood pressure and jaundice.

Only the third group of animals developed severe kidney damage, he said.

STANFORD--Mrs. Ludmila Davis, R.N., director of the operating room and emergency room at Stanford University Hospital, won the top writing award at the national congress of the American Operating Room Nurses Association held last week in Cincinnati.

The award, which carries a $300 prize, was given for the best article of the year in AORN Journal, the association's monthly magazine.

Her article, entitled "Reflections on Heart Transplantation," described the feelings of the operating room nurses at the time of the first heart transplant operation at Stanford (January 6, 1968) and paid tribute to the support the nurses gave surgeon Norman B. Shumway and the members of his heart transplant team as they made the historic step forward.

Mrs. Davis joined the Stanford University Hospital staff as director of the operating room in 1965.

(ADVANCE) FOR RELEASE WEDNESDAY, MARCH 12, 1969.

STANFORD--Two Stanford University medical researchers now are experimenting with animals to determine if electric shock may be the answer to quickly raising and maintaining a patient's white blood cell level count to combat infections.

They are studying collie dogs which have cyclic neutropenia, an inherited blood disease marked by abnormally low levels of white blood cells. The dogs die usually from infections during acute stages of the disease.

One reason for the study is to determine the effect of electric shock on white blood cell levels as well as the amounts of shock needed for the white cells to rise.

The researchers are Dr. Paul L. Wolf, associate professor of pathology and director of clinical laboratories at Stanford University Medical Center, and Dr. John Lund, instructor in pathology and veterinary pathologist. Dr. Wolf described the study today at the annual meeting of the International Academy of Pathology at the San Francisco Hilton Hotel.

"If a way were found to stimulate white cell production sufficiently through safe electric shock, then the tedious requirement for transfusing white cells to patients would be eliminated," Dr. Wolf said.

White blood cells are the body's infection fighters. Some white cells called lymphocytes act selectively to combat virus infections as the common cold. Other cells combat bacterial infections such as bacterial pneumonia. These are called neutrophilic cells and comprise 50 to 60 per cent of the white cells in human blood.

"The study has a particular clinical interest at this time," said Dr. Wolf, "because infections--pneumonia among them--have been blamed as a cause of death for kidney and heart transplant patients despite massive white cell transfusions. This is because drugs used to combat rejection of foreign tissue also lower the white blood cell count in patients, rendering them susceptible to infections." -more-

The fact that electric shock causes an increase in the white cell count of patients came to Dr. Wolf's attention two years ago, when he was on the faculty of Wayne State University in Michigan.

He said he studied a young fireman whose white blood cell count showed an unusually high elevation after being struck by a falling high voltage electrical wire during the Detroit riots.

Observations made during the first week showed the fireman's white blood cell count shot up to 32,000 to 45,000, to 57,000, and then to 117,000 per cubic millimeter, Dr. Wolf reported. A count of up to 11,000 is normal.

"We felt that the electric shock was the direct cause for the white cell increase," Dr. Wolf said.

"We are certainly aware that such a reaction may result from extensive burns, severe infection, hemorrhage, and other conditions," he added, "but none of these were present, and it was thus the clinical impression that the electric shock produced the white cell increase."

Subsequently, Dr. Wolf studied variations in white blood cells of 24 psychiatric patients who were receiving electroshock for therapeutic reasons.

By measuring their white blood cell count before and after mild electric shock was given, he found that 75 per cent of the patients had developed an increase in white (neutrophilic) blood cells. The level of increase ranged from 50 to 100 per cent over the level prior to electric shock.

This unusually high blood cell count, developed within 2 to 4 hours after the electric shock, persisted for 12 to 24 hours. In 20 per cent of the patients, the white blood cell rise ranged from 25 to 50 per cent above the base level and persisted for about 12 to 16 hours.

Five per cent of the patients showed no occurrence of the blood condition. This is an anticipated response, Dr. Wolf explained, since a small percentage in any population does not react to certain forms of treatment or medication.

Dr. Wolf noted that the mechanism for the white blood cell response to electroshock is not well defined. But, he added, "direct stimulation of the pituitary-adrenal system by electric shock is known to release cortisone or adrenalin which may be responsible. Other factors may also be involved."

Lila Motley Cancer Foundation 212: 759-4245

NEW YORK -- Dr. Henry S. Kaplan, professor and chairman, Department of Radiology at Stanford University School of Medicine, is the 1969 recipient of the Lila Motley Award and Shahbanou Medal. Announcement of the award was made today by the Lila Motley Cancer Foundation.

As part of the award, Dr. Kaplan will make a trip to Iran to conduct seminars and visit clinics in an exchange of ideas in the fight against cancer.

Dr. Kaplan will receive the award and the Iranian gold medal at the Foundation's Peacock Ball in New York this Saturday, May 3. The Ambassador to the United Nations from Iran, Mehdi Vakil, will present the Shahbanou Medal on behalf of Empress Farah of Iran.

This award to Dr. Kaplan comes on the heels of another major honor: earlier this week he was named an Atoms for Peace Award winner for his achievements in the peaceful uses of atomic energy.

The Lila Motley Cancer Foundation was organized by a group of New York women in honor of Lila Motley, who was a victim of cancer. In addition to supporting activities which contribute to the dissemination of cancer research results to physicians in other countries, the Foundation sponsors cancer-related projects at New York University Medical Center.

Editors: Story released simultaneously with announcement to be made Tuesday, April 29 by Atoms for Peace Awards, Inc., Cambridge, Mass.

(ADVANCE) FOR AM RELEASE TUESDAY, APRIL 29, 1969

STANFORD -- Dr. Henry S. Kaplan, a pioneer in radiobiology and the application of supervoltage and electron beam therapy in cancer, was named today a recipient of the Atoms for Peace Award.

He is one of seven scientists from four countries selected to receive Atoms for Peace Awards for pioneering work in peaceful uses of atomic energy in the last decade.

These awards, and the previously announced award to the late Dwight D. Eisenhower, will be presented May 14 in Washington, D.C. They will conclude a program begun 14 years ago to recognize distinguished contributors to the peaceful uses of the atom.

In addition to Dr. Kaplan, other award recipients announced today include Aage N. Bohr and Ben R. Mottelson of Denmark; Floyd L. Culler, Jr., and Anthony L. Turkevich of the United States; M. S. Ioffe of the Soviet Union; and Compton A. Rennie of England.

In announcing this group of awards, Dr. James R. Killian, Jr., chairman of the Atoms for Peace Awards trustees and chairman of the Massachusetts Institute of Technology, said that the intention of the trustees is "to recognize a relatively younger group of scientists and engineers whose recent achievements illustrate some exciting ways in which we are putting atomic energy to peaceful work and to show how widespread these efforts are throughout the world."

Dr. Killian said the trustees "hope that this recognition will stimulate the scientific and political communities to find more ways to use the atom to extend our knowledge and the control of the physical world, and to alleviate some of the problems in attaining the full life for all men."

Counting today's recipients, 22 people from eight nations have been named to receive the Atoms for Peace Awards. The seven recipients announced today will each receive a gold medallion symbolizing the award, and each will also receive an honorarium of $15,000.

Dr. Kaplan was cited for research which has contributed to understanding how radiation induces leukemia in mice, and for the development of the "cancer gun" at Stanford University Medical Center. He was also cited for his introduction of radiation biology into clinical radiation therapy training programs.

When Dr. Kaplan organized the Department of Radiology at Stanford 20 years ago, he felt that early work in radiology had been done by physicians whose prime orientation was toward pathological anatomy, perpetuating an emphasis on static images. "It was clear to me that the stature of the field depended upon research," he told an interviewer recently.

-more-

He founded the department with two points of research emphasis. The first was encouragement of the study of motion--blood flow and valve action--in diagnostic radiology, which represented a movement into applied physiology. The other point, in radiation therapy, was an effort to understand radiation biology.

After graduating from Rush Medical School in 1940, Dr. Kaplan served his internship and residency at Michael Reese Hospital. He then went on to the University of Minnesota, Yale, and the Public Health Service before coming to Stanford in 1948.

Three years later he asked the Stanford physics department to investigate the possibility of adapting a new high-energy physics device, the linear accelerator, for medical application. After helping design the necessary apparatus, he set standards for its use.

"It was like getting a new high-powered rifle," Dr. Kaplan recalls. "You couldn't go out and use it like an old shotgun."

The linear accelerator technically liberated Dr. Kaplan and his associates to further work on Hodgkin's disease and other malignant cancers.

With the megavoltage beam, he was able to irradiate a larger area and consequently developed "the mantle technique," which allowed irradiation of all the lymph nodes of the neck and thorax at one time. As a result, he records an 80 to 90 per cent cure rate for early stages of Hodgkin's disease, and more recently succeeded in obtaining five-year survivals in advanced cases as well.

Dr. Kaplan has also dispelled the theory that, in leukemia, X rays and chemical agents mutate the cells so they behave as cancer. In his work with mice, he has shown an indirect induction mechanism whereby irradiation or a chemical trigger a latent virus.

He has been able to pinpoint the target cells for the leukemia virus in mice and has been able to define the mechanism by which bone marrow inhibits the development of leukemia unless irradiated.

Dr. Kaplan also has shed much light on the fundamental biologic effects of radiation. He and others have gathered overwhelming evidence that DNA (the cell's hereditary material), is the target molecule in the cell for radiation effects. With this information, Dr. Kaplan has been developing drugs which are picked up by the DNA and increase radiation sensitivity. He has now moved some of these studies to the clinical stage.

At the Award ceremony, which will be held at the National Academy of Sciences, the trustees will also present posthumously to the late Dwight D. Eisenhower the Atoms for Peace Award announced March 20.

The Atoms for Peace Awards program was established as a memorial to Henry Ford and his son, Edsel, in 1955, when the Ford Motor Company donated $1 million to support the presentation of annual awards for the advancement of the science of atomic energy for peaceful purposes. Atoms for Peace Awards, Inc. at Cambridge, Mass. was created as a nonprofit corporation to receive and administer the funds.

ADVANCE FOR RELEASE THURSDAY, APRIL 17, 1969

ATLANTIC CITY -- A naturally occurring body chemical, dopamine, has been found to restore normal heart function in dogs after an acute heart attack.

The finding, reported today by a Stanford University medical research team, was termed "encouraging" and may represent a new approach to treating patients with extensive heart damage.

The Stanford researchers first tested the drug for its circulatory effects on 17 dogs with normal hearts. They found that dopamine enhanced overall blood circulation and heart performance.

Then the researchers gave the drug to the same dogs after they had suffered heart attacks induced surgically. The technique used to produce heart attacks allowed the exact estimation of the size of muscle damage which averaged 37 per cent of the heart.

The drug, according to the researchers, reversed all the abnormalities in circulation caused by the heart attacks in the animals. It increased the strength of their heartbeats, and the capacity of the damaged muscle to pump blood to near-normal levels, and eliminated all signs of heart failure.

The new finding was reported at the meeting of the Federation of American Societies for Experimental Biology. The researchers are Bruce U. Wintroub, Dr. John S. Schroeder, Dr. Marianne Schroll, Mrs. Sherilyn Robison, and Dr. Donald C. Harrison. Their work was done with grant support from the National Institutes of Health.

Dopamine's circulatory effects have been known for some time. The drug has been used successfully in the treatment of shock. It is a precursor in the synthesis of the compound norepinephrine, associated with the regulation of blood pressure in the heart.

This is believed to be the first controlled animal study of the drug's effects in the treatment of acute heart attack (myocardial infarction), according to the researchers.

The studies, the researchers said, have shown that dopamine "may be of extreme value in treating patients with extensive cardiac damage. It appears to increase the function of the heart in a manner which makes it superior to other agents now available."

This premise, however, needs to be tested in a large patient population with acute myocardial infarction, they added.

Clinical tests of the drug in patients with acute myocardial infarction are now under way at Stanford University Hospital.

FOR AM RELEASE THURSDAY, APRIL 17, 1969

STANFORD--The possibility that stroke, which ranks third among the leading causes of death in the United States, can be predicted and prevented is suggested by a research team from NASA Ames Research Center and Stanford University School of Medicine.

Working under grants from the National Aeronautics and Space Administration and the National Heart Institute, the researchers have now developed a technique which may identify stroke-prone patients.

The researchers are Donald L. Ciffone of NASA Ames Research Center at Moffett Field, California; John W. Gamel, a Stanford medical student; Dr. William H. Marshall, Jr., assistant professor of radiology; and Dr. Leo A. Sapirstein, professor of physiology in Stanford's department of radiology. Their work was described today at the meeting of American Societies for Experimental Biology in Atlantic City.

The new technique consists of injecting a radioactive drug (Technetium Tc^{99m}) into the blood stream and then measuring its flow rate as it passes through the patient's brain.

The records obtained by a scintillation detector and accessory equipment are analyzed by computers, which calculate the pattern of blood-flow rate through the brain.

"An indication of a low blood-flow rate might be the result of a hardening and narrowing of the arteries of the brain," the researchers explained. "In such a case, it is expected that the blood-flow pattern will display the characteristics of a stroke-prone patient."

The cerebral stroke, an interruption of the normal blood supply to the brain, is usually a result of arterial deterioration.

When a stroke candidate is identified, his physician may prescribe medical treatment to prevent a stroke. Surgery to remove the arterial obstruction, or use of anticoagulant drugs are among the most common preventive measures used.

The researchers described their technique as "simple," and "safe." "This test does not cause any more discomfort to the patient than that which he would experience if a simple blood sample were drawn for any other type of analysis," they said.

Ciffone and Gamel developed the analytical methods which interpret and analyze the isotope measurements, and a fluid mechanical model which simulates the blood-flow characteristics through vessels to allow verification of the technique.

Measurements to establish normal brain blood-flow rates and patterns, as well as deviations from these in disease have been made at Stanford University Medical Center by Drs. Marshall and Sapirstein.

The researchers predicted that, although not routine, the technique may have a wide clinical application and may aid significantly in reducing the incidence of stroke.

END OF RELEASE FOR AM THURSDAY 4/17/69.

Aided by laboratory assistant James Bradley, Dr. William H. Marshall, Jr. of the Stanford University School of Medicine, demonstrates new test used in diagnosis of stroke. Miss Louise Lyman, a laboratory technician posing as a patient, "receives" injection of radioactive drug which permits physicians to record and calculate patterns of blood-flow rate through the brain. A low blood-flow rate means that patient may be suffering from hardening or narrowing of the arteries--a danger signal. The technique was developed by scientists at Stanford and NASA Ames Research Center.

STANFORD -- A 58-year-old man from Bakersfield, California became the 13th heart transplant patient Sunday at Stanford University Hospital.

The recipient is James E. Pounds. He received his new heart in a 4-1/2 hour operation performed by a team of surgeons headed by Dr. Norman E. Shumway.

Donor of the heart was 21-year-old Gary Ostrom of Palo Alto, who suffered irreversible brain damage in an auto accident Friday. Ostrom, father of a 4-month-old son, Gary Allen, Jr., died Sunday morning at the Hospital. He is survived by his wife, Carol, his son, his mother, Mrs. Grace Ostrom, two sisters, Mrs. Nancy Driskell of Mt. View and Mrs. Yvonne Brawner of Redwood City, and a brother, Daniel C. of Eugene, Oregon.

EDITORS: The following story written by Spyros Andreopoulos of the Stanford Medical Center News Bureau. Smith may be contacted directly at 325-3305 or 321-1200, ext. 5811.

FOR IMMEDIATE RELEASE

STANFORD - "How do nerve gases work?" "Why are viruses so deadly?" "What are the effects of massive defoliation programs on human, plant and animal life?"

These and related questions will be discussed Thursday (APRIL 10) at a science fair organized by a group of Stanford University graduate students "to dramatize the perils and implications of chemical and biological warfare research on living things."

Exhibits ranging from how to grow deadly bacteria to delivery systems of lethal gases and other chemical and biological warfare weapons will be open for the public at 7:30 p.m. in Tresidder Memorial Union, and will be followed by informal discussions led by students.

The event, organized by Andy Smith, a graduate student in neurological sciences and a member of the Chemical-Biological Warfare Study Group at Stanford, is sponsored by the Stanford Research Institute Coalition, a group of students and faculty members favoring stricter University control of Stanford Research Institute programs.

Smith said there is a need to educate the layman about the nature of research done on chemical and biological warfare. "By bringing together graduate students with specialized experience in such fields as neurochemistry, virology, and plant physiology, I hope these questions can be answered," he said.

At the same time, Smith added, actual demonstrations of such work would allow students to understand chemical and biological warfare research far better than if they merely listened to lectures on the subject.

Smith, who is a member of the SRI Coalition, said another purpose of the fair is to bring closer to home SRI's role in classified research.

"Basically we feel that SRI, as a University-related institution, should not be allowed to conduct research designed to harm people," Smith explained. "At present, most of this research is classified.

"We feel that if SRI were made a more official part of Stanford University, it would be possible to insure that no classified projects be undertaken by the Institute.

"Then, with full knowledge of what was being studied, the Stanford-SRI community could judge whether such research were in line with the statement from the SRI charter, 'for peace and prosperity of mankind.'"

Topics at the science fair and graduate students presenting them include nerve gases, Andy Smith (neurosciences); defoliation-herbicides, Terry Chapin (biology); bacteria, George Johnson (biology); viruses, Dale Hattis (genetics); distribution of CBW agents, Mel Kronik (physics).

In addition, Dr. Robert Karpf of the Santa Clara Valley Medical Center, will discuss chemical and biological warfare agents from a medical standpoint. His lecture will be on "Problems in Detection, Protection, and Treatment."

A pearl ring, a copper sculpture of the figures from the painting "American Gothic," and a black and white photograph of an old codger on a New York City sidewalk were among the winners of this year's art show at Stanford University Medical Center.

The recent show was the most successful ever held at the Medical Center, with a record 209 entries. Students, faculty, personnel and volunteers were eligible to participate.

Nursing supervisor Lois Perry of Los Altos crafted the ring, which consists of two cultured pearls mounted on a delicate silver band.

The copper sculpture, entitled "Grant Wood U.S.A.," was done by Research Associate in surgery Dr. Raymond Stofer of Woodside, who has won top prizes five of the six years the show has been held.

In the black and white photo, fourth year medical student Eugene Altman of Palo Alto had captured reflections of New York apartment buildings glinting off the glasses of his unshaven subject.

Other first prize winners were graduate student in biochemistry Thomas Broker of Menlo Park, for his color photograph "Processional," a title extrapolated from the view of Bridal Veil Falls; Dr. R. Wesley Wright of Atherton for his oil painting "Coast House," nursing clerk Judy Pantages of Los Altos for her drawing "Self Portrait 1966-1967;" Dr. Wright again for his watercolor "Monterey Wharf;" Dr. A. M. Gottleib of Menlo Park for an abstract oil painting "Stained Glass Window;" and Dr. Arnold Starr of Palo Alto for "Isenberg Ranch," an acrylic.

Professional judges made the choices, awarding 25 prizes and 14 honorable mentions.

The judges were Mrs. Dagmar Dern of Redwood City, a member of Peninsula Stitchery Guild and Bay Area Arts and Crafts; Ray Lorenzato and Gilbert Steed of San Mateo, both art teachers at the College of San Mateo; Mrs. Lyman Page of Palo Alto, a member of the Palo Alto Art Club and Paul Engelcke of Palo Alto, a member of the Palo Alto Camera Club.

Mrs. Alice B. Mild of Portola Valley, head of the Medical Center's housekeeping department, was chairman of the ten-member committee which organized the show.

STANFORD -- Dr. Norman Kretchmer has been chosen as the 1969 recipient of the Alumni Medallion for Distinguished Service to American Medicine, by his alma mater, the College of Medicine of the State University of New York.

A 1952 alumnus, Dr. Kretchmer is professor and chairman of the Department of Pediatrics at Stanford University School of Medicine.

The medallion will be presented at Downstate Medical Center Commencement ceremonies Thursday, June 5 at 8 p.m. in the Walt Whitman Auditorium of Brooklyn College.

Dr. Kretchmer is internationally known for pediatric research, and for basic research in biochemistry. He is responsible for expanding the scope of Stanford pediatric programs by focusing work on the molecular, physiologic and behavioral aspects of growth and development. He obtained the first award from the National Institutes of Health for construction at Stanford of a clinical research center for premature infants.

He also established a major research and training program in the field of developmental biochemistry. This is a new field which unites clinical and research efforts directed toward a biochemical understanding of congenital defects, metabolic diseases, and mental retardation.

The Stanford professor recently announced he will relinquish the Department chairmanship in the fall of 1970 to return to full-time teaching and research. He has held the administrative post since 1959.

STANFORD -- A 33-year-old professional organist became the 14th heart transplant patient at Stanford University Hospital today.

The recipient is Ralph Trout III, 1625 Diel Dr., Milpitas. He received his new heart from an anonymous donor in an operation performed by a team of cardiovascular surgeons headed by Dr. Norman E. Shumway. Trout is reported in satisfactory condition.

Trout, who has also worked as an organ salesman, has suffered a series of heart attacks in the past four years. His family includes his father, Ralph Trout of El Sobrante, and a brother, Charles, of Milpitas.

STANFORD -- Two guest lecturers and nine medical students will give talks at the Ninth Annual Stanford Medical Student Day, Saturday May 24.

Dr. Philip R. Lee, chancellor of the University of California Medical Center in San Francisco, will deliver the Fourth Annual Lowell Rantz Memorial Lecture, the highlight of Student Day.

Dr. Lee, a 1948 graduate of Stanford University School of Medicine, was assistant secretary of Health, Education and Welfare before he was named to the University of California post.

Congressman Allard K. Lowenstein (Dem. - N.Y.) has also been invited to address the gathering of students, alumni and faculty. Recently Inter-Fraternity Guest-in-Residence at Stanford, Lowenstein will speak on "Social and Political Implications of Medical Education."

Student Day Chairman Robert C. Aber, fourth year medical student, will make the opening remarks when the Day's program begins at 12:30 Saturday in Room M106. Dr. Robert J. Glaser will give the Dean's welcome, and Dr. William H. Clark, president of the Stanford Medical Alumni Association, will give the welcome for the Alumni Association and present awards to the nine student speakers. Dr. Clark will also present the Association's Alumni Scholar Awards to Michael P. Alexander of the fourth year class and Ronald D. Adler of the fifth year class. Topics of student papers this year range from psychology to biochemistry to social issues, Aber said. The papers which are being given were selected by a committee of five students headed by M. Eric Gershwin, a member of the third year class.

Following the afternoon's program, the students will hold a reception and a dance.

Student Day is supported by the Stanford Medical Student Association, the Stanford Medical Alumni Association and the Palo Alto Clinic.

STANFORD -- Dr. Kenneth D. Gardner, assistant professor of medicine, is resigning from the Stanford faculty to join the faculty of the University of Hawaii School of Medicine on July 1.

His appointment was announced by Dr. Windsor Cutting, dean of the University of Hawaii School of Medicine. Dr. Cutting was formerly professor and chairman of the department of pharmacology and dean (1953-1957) at Stanford Medical School.

Currently a two-year program, medical education at Hawaii is expected to be expanded to a full four-year program in the early 1970's. Dr. Cutting was instrumental in establishing the School, which admitted its first class in 1967.

The 50th State's interracial and tropical aspects make it an excellent setting for specialization in genetics and tropical medicine, commented Dr. Gardner.

At the University of Hawaii, he will be professor of medicine, chief of the renal division of the Department of Medicine, chairman of the admissions committee of the School of Medicine and a consultant in medical education for the Regional Medical Program of Hawaii.

The last mentioned assignment is a particularly exciting prospect to him, because the Hawaii RMP area takes in the United States Trust Territories of the Pacific, including the Marshall and Solomon Islands and American Samoa. "This remote area of the world offers a unique challenge for the education of the nurses, technicians and physicians needed to care for its people, as well as providing an excellent laboratory for field work in the delivery of medical care," Dr. Gardner said.

Two of Dr. Gardner's major research projects at Stanford have been: first, a six-year study, done in collaboration with Dr. Roy H. Maffly, on the permeability of the distal nephron (the functional unit of the kidney) to urea; and second, a study(which he will continue in Hawaii) of a genetically transmitted and unusual form of kidney disease known as cystic disease of the renal medulla.

While on the Stanford faculty, Dr. Gardner was named an "outstanding teacher" by the medical students of the classes of 1971 and 1972.

He is a native of San Francisco, and received both the B.M.S. (1951) and M.D. (1955) from Stanford. He served his internship and residency at the Hospital of the University of Pennsylvania, and returned to Stanford as a research fellow in 1961, joining the faculty as an instructor in 1963. He has been assistant professor since 1964.

When the Gardners (Mrs. Gardner is the former Dorothy Rowe of Palo Alto and a 1953 Stanford graduate), move to the Islands, they will make their home in Kailua on Oahu. They have four daughters, ranging in age from two to 13 years.

ADVANCE FOR PM RELEASE WEDNESDAY, MAY 7, 1969

BAL HARBOUR, FLA.--Psychiatric complications resulting from the trauma of major surgery and anti-rejection drugs are not uncommon in heart transplant patients, a Stanford University psychiatrist said today.

Dr. Donald Lunde, speaking at the annual meeting of the American Psychiatric Association, said that while in the majority of cases the psychiatric complications have been temporary and of short duration, three patients did develop serious psychiatric problems postoperatively.

His remarks were based on observations during the last 18 months as psychiatric consultant on Dr. Norman Shumway's heart transplant team at Stanford University Medical Center.

"The personality changes which we have seen are not surprising," Dr. Lunde said. "It is well documented that patients on steroid drugs often have temporary psychotic reactions. It is also known that these reactions occur in patients who have been on a heart-lung machine as is necessary in open heart or heart transplant surgery or who have been confined for lengthy periods in an intensive care unit.

"The heart transplant patient is subject to all three of these conditions," he pointed out.

"There are usually changes in the patient's perception of himself following the operation," according to Dr. Lunde. "The patient who has previously been an invalid suddenly, and in some cases very dramatically, is rather healthy and has a significantly increased exercise tolerance. Patients who had been bedridden and could not walk across a room can walk up and down the hospital corridors a week after the transplant operation.

"Some of the patients have also felt that by receiving the heart of another person they might take on some of the personality characteristics of the donor. One patient, who knew the background of the heart donor, said he felt he had an obligation to live up to the standards set by the man whose heart he had received."

Dr. Lunde said that psychiatric evaluation of potential heart transplant recipients prior to the operation is important.

-more-

"In addition to the medical criteria of accepting only those patients who have severe and incapacitating heart disease, they are also screened for any evidence of psychosis or severe depression," the Stanford psychiatrist said.

"It is vitally important that the potential heart transplant patient be fully capable of understanding the risk of known complications as well as the possibility that unforeseen problems may arise at any time after the operation," Dr. Lunde said. "An individual suffering from a mental disorder which prevents him from realistically evaluating these risks and giving an informed consent for the operation has been considered an unsuitable candidate for this procedure."

At least two potential candidates have been ruled out for such reasons, he said. The three patients who developed psychoses postoperatively had manifested no evidence of psychiatric problems before the operation.
